I. GENERAL DESCRIPTION OF AIR MONITORING PROGRAM

Radian Corporation is under contract to C-b Shale Oil Project to provide ambient air quality monitoring.* Each site measures and records the concentration of particulates, sulfur dioxide, and hydrogen sulfide. In addition, two of the sites record the amounts of nitrogen oxides, total hydrocarbon, methane, ozone, and carbon monoxide. Selected meteorological parameters such as wind speed, wind direction, temperature, and rainfall are monitored at each station. A 200-foot meteorological tower at one of the sites provides meteorological information as a function of height. Meteorological instrumentation is planned at the 8, 30, 100 and 200-foot levels.

Figure I shows a typical configuration of each monitoring station. The station enclosure provides a sturdy and protective covering for the monitoring equipment.

*Five monitoring sites are located in Northwest Colorado in the Piceance Creek Basin on or near the Federal Oil Shale Tract C-b.

Figure 1

II. DESCRIPTION OF INSTRUMENT SYSTEMS

A. Air Quality Instrumentation

Nitrogen oxides are measured with a Meloy Model NA520 analyzer. This dual-channel analyzer is based on the chemiluminescent principle, and continuously monitors both NO_x and NO . A subtraction circuit in the instrument provides a continuous NO_2 output, but is not used in Radian's system. NO_2 is calculated once a second by the computer by subtracting the NO value from the NO_x value, thus avoiding any drift which might occur in the NO_2 output of the instrument. This instrument has a minimum detectable sensitivity of 5 ppb (parts per billion), and a linearity of 1%.

Both sulfur dioxide and hydrogen sulfide are measured with Meloy Model SA185 sulfur analyzers. The hydrogen sulfide analyzer uses a Meloy Model SO_x -1 sulfur dioxide scrubber and the sulfur dioxide analyzer uses a Meloy Model H_2S -1 hydrogen sulfide scrubber. The Model SA185 is a continuous analyzer, and utilizes the flame photometric principle of operation. The minimum detectable sensitivity is 5 ppb, and the linearity is $\pm 1\%$.

Ozone is measured with a Meloy Model OA350 analyzer. This instrument provides continuous measurement of ozone, and is based on the chemiluminescent principle. The minimum detectable sensitivity is 0.5 ppb and the linearity is 1%.

Total hydrocarbons, methane, and carbon monoxide are monitored with a Bendix Model 8200 gas chromatograph analyzer. This instrument uses a flame ionization detector and has a minimum detectable sensitivity of 5 ppb for all three components. The Model 8200 works on a five-minute cycle, i.e., one air sample is analyzed every five minutes, and the result is displayed for five minutes via a sample and hold circuit.

The air sample is drawn in through a glass cane and manifold supplied by the Ace Glass Company. The system has a 25mm diameter, and a constant air flow through the system is provided by an air pump rated at 60 cfm at 0" head pressure. The manifold has sampling ports to which $\frac{1}{4}$ " teflon lines to the instruments are connected. All joints in the sampling system are secured by O-ring (Viton-A) compression fittings. The manifold is contained in a heated (100°F) chamber to prevent condensation of moisture. The teflon lines from the manifold to the instruments are insulated with 1/8" wall thickness rubber tubing.

The trailer has four heavy duty high volume particulate samplers (Hi-Vols). Fiberglass filter paper is used for collection of particulate samples, and each filter is brought to a controlled humidity before weighing. Each Hi-Vol has a flow recorder to permit correction for changes in air flow as the filter becomes loaded with particulates. Each Hi-Vol runs for a 24-hour period (midnight to midnight), and is turned on and off by the computer. The Hi-Vols were designed following guidelines recommended by the Environmental Protection Agency and were manufactured by Radian.

In addition to the normal Hi-Vol particulate samples, a duplicate Hi-Vol sample is collected every sixth day on special filter paper for trace element analysis. Once each quarter these samples are composited and analyzed for gross radioactivity and trace element content.

B. Calibration Procedures

Each trailer contains a Meloy Model RAD-1 calibration unit. This instrument provides a zero air supply, SO₂ span gas from an SO₂ permeation tube, and NO span gas obtained by precisely diluting bottled NO span gas. The calibration of all instruments is automatically performed once a day, and is controlled by the computer. Each instrument is first switched to zero, and the computer monitors the output of each channel and takes a new zero reading after a stable zero signal has been reached. This zero reading is compared by the computer to the zero reading obtained 24 hours before, and if a drift in excess of 10ppb has occurred, an excess zero drift light for the channel in question is turned on on the System Status Panel. Next, the span gas is supplied to each channel and the computer decides when a stable span value has been reached. This value is recorded and compared to the previous day's value. An excess span drift light on the System Status Panel is turned on if a drift exceeding 10ppb occurs. The instruments are then returned to the monitor mode, and after two minutes the computer resumes data taking. If an excess drift light is turned on, the operator will note this after entering the trailer, and obtain the calibration data from the computer via the printer. The operator decides whether the drift is severe enough to warrant discarding the previous data, and he then performs a manual calibration to determine if the instrument requires servicing. If so, the instrument is repaired.

The SO₂ permeation tubes were manufactured by Metronics Association, Inc. Their output has been verified by comparison to the output of National Bureau of Standards tube 10-42. Both SA185 analyzers in each trailer are calibrated with SO₂ from the permeation tube. This instrument responds to the number of sulfur atoms per molecule, thus SO₂ can be used to calibrate both the H₂S and SO₂ monitors. The zero air is obtained by passing ambient

RADIAN CORPORATION

air through an activated charcoal column. These columns are replaced every three months.

The Model OA350 ozone analyzer has its own calibration system which provides a zero check and a span check. The zero air is obtained by passing ambient air through an activated charcoal column (replaced every three months). The span gas is obtained by passing zero air through a calibrated UV source. The ozone calibration system is verified by comparison to a calibrated ozone generator maintained in Radian's laboratory in Rifle.

The Model 8200 total hydrocarbon, methane, and carbon monoxide analyzer is calibrated with undiluted span gas obtained from AirCo's Rare and Specialty Gas Division. This span gas contains methane and carbon monoxide in air, the methane being used to calibrate both the total hydrocarbon channel and the methane channel. This span gas is checked against a bottle of span gas which was calibrated at the National Bureau of Standards. The Model 8200 is zeroed with air from a Bendix Model 8834 zero air unit (a molecular sieve dryer plus catalytic oxidizer). In addition, the instrument is electronically re-zeroed at the start of every five-minute cycle.

Bottled NO span gas is used for calibration of the nitrogen oxide analyzers. Bottles from three different manufacturers are used, and these agree with each other within 3% (Precision Gas Company, Linde Specialty Gas, AirCo Specialty Gas). The zero air is obtained by passing ambient air through an ozone generator (to convert NO to NO₂) and then passing it through two charcoal filters (replaced every three months). Bottled NO span gas has recently become available from the National Bureau of Standards and a bottle has been ordered.

RADIAN CORPORATION

The Hi-Vol particulate samplers were calibrated using a Calibration Kit from General Metal Works.

C. Data Acquisition System

The basis of the data acquisition system is a Data General NOVA 1200 minicomputer. The NOVA which has a basic cycle time of 1.2 μ sec is equipped with automatic program load and power fail/automatic restart features. The computer utilizes 16K 16-bit words of core memory. Analog-to-digital conversion is accomplished via an ADC built by Radian Corporation. The input/output unit for the system is Texas Instrument's KSR 733 keyboard/printer. This model teletype provides keyboard entry and hard copy printed output. The data are also recorded on a cassette magnetic tape unit with three drives. The cassette unit is utilized for program storage and loading as well as recording. The power to the teletype and cassette units is turned on only when the unit(s) is to be used to reduce wear on mechanical parts. Several important functions in the instruments as well as in the computer and the trailer are monitored by means of lights on a System Status Panel. These data lights are written onto cassette tape to monitor the complete status of the system every five minutes. The Data Acquisition System also monitors the presence of 110V power from the power lines. In its absence, the computer, which is powered by batteries, switches all trailer systems to battery-provided power. If the line voltage is restored before the batteries are discharged to a specified level, the trailer system is switched back to line power.

D. Meteorological Instrumentation

1. Ambient Air Monitoring Trailers

Four of the ambient air monitoring trailers are equipped with the following meteorological instrumentation: (1) dry bulb temperature (outside), (2) relative humidity, (3) wind direction, (4) wind speed, and (5) a tipping bucket, heated rain/snow gage. The temperature probe and relative humidity sensor are mounted inside a motor aspirated radiation shield, the Model 1S6 Aspirated Radiation Shield by Weather Measure, which gives an aspiration of approximately 100 cfm. The wind instrumentation and temperature and relative humidity apparatus (in the aspirated radiation shield) are all mounted atop a 30-foot crank-up meteorological tower (the WM-33, by Weather Measure) at each of the four trailer sites.

The wind instrumentation at the monitoring trailers consists of the Model W103/3L Lightweight Cup Anemometer by Weather Measure and the Model W104-2 Lightweight Vane by Weather Measure. The anemometer is a high response, low threshold wind system which offers the optimum in versatility and economy. For low threshold applications, a unique frictionless tachometer employing a high frequency oscillator and receiver is used to measure precisely wind speed. The oscillator, transmitter, and receiver are encapsulated in a small cube of epoxy for total protection against the environment. The high frequency tachometer embodies several distinct advantages over the commonly used light chopper systems. There are no light bulbs or photocells to burn out; power consumption is low; and the system is insensitive to moisture condensation or dust deposition. The solid state tachometer is essentially free from maintenance with a life of well over five years when operated continuously. The specifications of the W103 Cup Anemometer are as follows:

- Accuracy: $\pm 1\%$ or .15 mph, whichever is greater.
- Bearings: Sealed and shielded precision stainless steel.
- Threshold: 0.6 miles per hour
- Distance Constant: 5 feet

The wind vane, the W104-2, is equipped with a 1000 ohm low torque potentiometer and two wipers for 0° to 540° operations. The response characteristics of this vane are:

- Dead Band: 0 degrees
- Damping Ratio: 0.4
- Distance Constant: 3.5 feet
- Threshold: 0.75 miles per hour
- Potentiometer Linearity: 0.5%

The thermistor probe used in the motor aspirated radiation shields is the Model T621-TP18X Air Temperature Premium Thermistor Probe by Weather Measure. This probe has a range of -50°C to $+50^{\circ}\text{C}$ and an interchangeability of $\pm 0.055^{\circ}\text{C}$. The output signal accuracy is $\pm 0.3^{\circ}\text{F}$.

The relative humidity sensor is the Model 2013 Remote Reading Relative Humidity System by Texas Electronics. The sensor assembly contains a newly-developed hygroscopic inorganic sensing

element. Its expansion and contraction positions the suspended core of a linear variable differential transformer (LVDT). The absence of friction inducing linkages and wiping contacts minimizes hysteresis and improves accuracy. The LVDT output signal, when processed, is directly proportional to relative humidity. The specifications of this instrument are as follows:

- Range of Indication: 0% to 100% RH
- Response: The sensor response time to a step change of 10% in relative humidity is less than 2 minutes with the sensor exposed to moving air.
- Accuracy: 5% - 15% RH; $\pm 5\%$ RH
15% - 95% RH; $\pm 2\%$ RH
95% - 100% RH; $\pm 3\%$ RH
- Signal Output: Analog signal of -150 mv. to +150 mv. with electrical zero at 50% RH is standard.

Each of the four monitoring trailers is equipped with a Model P511-E Remote Recording Heated Snow Gage by Weather Measure. In the case of this gage, the durability and reliability of a tipping bucket gage are combined with heavy-duty electric heaters to make this an all-purpose precipitation sensor. This gage may be used to measure snowfall and rainfall. An insulating cover of poly-vinyl chloride and a thermostatic control insure the proper gage temperature. The thermostatic control is adjustable from 0 to 35°C. Snow falling into the inlet funnel is melted. The resulting water (from rain or snow) drains into a precision tipping bucket mechanism which activates a mercury switch each time the bucket fills and tips. The gage is constructed

of durable corrosion-resistant materials to provide many years of service. The specifications of this gage are as follows:

- Orifice: 8 inches
- Calibration: 0.01 inch
- Accuracy: 0.5% (Calibrated at 0.5 in/hr)
- Sensor: Chrome plated tipping buckets
- Switch: Mercury, 0.1 second closure
- Heat Control: Thermostat adjustment, 0 to 35°C.

2. 200-Foot Meteorological Tower

The tower has instrumentation at four levels: 8 feet, 30 feet, 100 feet, and 200 feet. At all four levels, there are: wind speed, wind direction, and temperature and relative humidity sensors in a power aspirated radiation shield. Temperature difference thermistors (also in power aspirated radiation shields) and their associated circuitry take lapse rate measurements for the 35-foot to 100-foot layer and the 30-foot to 200-foot layer. In addition, this site has a Precision Spectral Pyranometer, a barometer, and a tipping bucket rain/snow gage.

The wind direction and speed apparatus used at each measurement level of the tower is the Model 1074-2 wind sensor by Meteorological Research, Inc. (MRI). This sensor has a 540° potentiometer for wind direction and a light chopper for wind speed. This sensor is rugged, with an all-weather coaxial cup and

damped vane assembly. The prototype model has been in operation for years under the most demanding weather conditions, performing continuously with the utmost reliability. All of the wind sensors on the tower have been specially treated with a black paint which will promote warming of the exposed surfaces of the sensor and thereby reduce ice and snow accumulations on the moving parts of the apparatus. The specifications on the Model 1074-2 are as follows:

Wind Speed

- Starting Threshold: 0.75 mph
- Response Distance: 18 feet (63% recovery)
- Flow Coefficient: 7.9 feet/Revolution
- Accuracy: ± 0.4 mph or 1% (whichever is greater)
- Range: 0-100 mph

Wind Direction

- Starting Threshold: 0.75 mph
- Delay Distance: 4 feet (50% recovery)
- Damping Ratio: 0.5 to 0.6
- Accuracy (540° system): $\pm 1\%$
- Range: 0° to 540°

The relative humidity and temperature sensors are mounted within a power aspirated radiation shield at each tower level. All aspirators and sensors are of the Model 840 Series by MRI. The aspirated shielded housing is designed to provide maximum radiation protection to the sensor. Ambient air is drawn into the shield and across the sensors at approximately 15 feet per second. This intake air is essentially sampled from a hemispherical space which is approximately 3-inch radius from the tube opening. Speed of the incoming air at the periphery of this hemisphere is approximately 1 mph.

The temperature sensor is comprised of a dual thermistor and resistor network. This circuit provides a linear resistance change with an air temperature change. The relative humidity sensor is placed alongside the temperature elements inside the shield where it is exposed to a constant flow of air. Circulation to both sides of the sensing element produces accurate monitoring with a good response time. The specifications on the sensing elements are as follows:

Temperature

- Accuracy: $\pm 0.25^{\circ}\text{C}$
- Range: -50°C to $+50^{\circ}\text{C}$

Humidity

- Accuracy: $\pm 3.0\%$ RH
- Range: 0% to 100% Relative Humidity

Measurements of temperature difference are taken for two layers, the 30-foot to 100-foot layer and the 30-foot to 200-foot

layer. The thermistors and circuitry used for these measurements are separate from the thermistors measuring air temperature. The use of separate thermistors and circuitry to measure ΔT allows for much greater accuracy and resolution in the measurements, which is necessary for stability assessments. Two ΔT thermistors are at the 30-foot level, one is at the 100-foot level, and one is at the 200-foot level. All of these ΔT thermistors are mounted within power aspirated radiation shields. The specifications on the ΔT instrumentation are as follows:

- Accuracy: $\pm 0.1^{\circ}\text{C}$
- Range of ΔT Circuit
(Lower Level-Upper Level): $+4^{\circ}\text{F}$ to -8°F

All instrumentation, except at the ground level, is mounted at the end of 12-foot retractable booms. These booms are 3-inch box beams which are on rollers and can be retracted to the instrument platforms for instrument maintenance.

The meteorological tower itself is a 200-foot Rohn Model 80 Guyed Tower, designed for 40 pounds per square foot wind load with $\frac{1}{2}$ " of radial ice per EIA Standard RS-222-B, to support four levels of meteorological equipment. The material consists of tower sections with a tapered base, three retractable booms 12-feet long, three outside work platforms, an inside ladder for climbing, two base ground kits and one anchor ground kit. The cable-type Safety Climbing Device consists of a cable and attachment mechanisms with a locking sleeve and safety belt. The tower is lighted and painted according to FAA specifications.

The signals from the tower instrumentation are fed from multiple signal cables into transmitters mounted at the base of

the tower. After signals have been converted to analog signals, they are fed into a junction box, also at the tower base, where they are assimilated into one coaxial cable. The signals are then run underground within 3" PVC conduit to the A-to-D assembly, where they are processed. The transmitters are shielded and insulated from the elements. The signal cable is run underground in PVC conduit in order to minimize damage from the weather or various rodents in the region.

The auxiliary equipment at the tower site consists of a heated tipping bucket rain/snow gage, an analog barometer, and a Precision Spectral Pyranometer. The rain/snow gage is the Model P511-E unit by Weather Measure, with characteristics and specifications as described in Section 1. The barometer is the B242 Analog Output Barometer by Weather Measure. This barometer provides an output voltage that is linearly proportional to pressure. The specifications on this instrument, which is mounted inside the monitoring trailer at the site, are as follows:

- Range: Specially designed for the 100 millibar interval from 725 millibars to 825 millibars.
- Resolution: Infinite
- Linearity: ± 0.5 millibar, over the 100 millibar interval

The pyranometer at the site is the Eppley Precision Spectral Pyranometer. This instrument is used for the measurement of sun and sky radiation totally or in defined wavelength bands. The pyranometer is levelled and mounted atop a wooden stand $4\frac{1}{2}$ feet from the ground surface. Care has been taken to

eliminate the effects from all outside influences, such as reflection or shadows, on the pyranometer. The instrument characteristics are as follows:

- Sensitivity: 5 mv. per cal/cm²/min
- Independence: 300 ohms
- Temperature dependence: Sensitivity constant to within ± 1 percent over the ambient temperature range from -20 to +40°C
- Linearity: Response linear up to intensities of 4 cal/cm²/min
- Response Time: 1 second (i/e signal)

All instrumentation is factory calibrated and is field-calibrated at various intervals. Sling psychrometers are used to calibrate the humidity sensors, known temperatures and/or resistances are used to calibrate the thermistors, and an rpm calibrating unit is used to calibrate the anemometers. The wind direction instrumentation is aligned to true north (reference direction) by means of a surveyor's transit.

III. MICROMETEOROLOGICAL AND TERRAIN FEATURES

The Piceance Creek Valley and C-b Oil Shale Tract are situated such that many microscale meteorological phenomena affect the region where the ambient air monitoring units are located. In particular, the three units in the Piceance Creek Valley (Trailers 020, 021, and 022) are heavily influenced by a katabatic-anabatic flow regime. Trailer 023 and its associated 200-foot meteorological tower are located atop a plateau to the south of the valley, high enough to be affected mostly by gradient flow conditions. Trailer 024, located half-way between the valley and the meteorological tower, is affected by a mixture of the gradient and mountain-valley flow regimes.

Elevations in the monitoring network range from about 6200 feet above sea level at Trailer 021, near the Rock Creek School in the valley at the westernmost end of the monitoring network, to 6940 feet at the meteorological tower site (Trailer 023) atop the plateau within the Tract C-b itself. The largest gradients in elevation in this area, of course, occur at the Piceance Creek Valley walls. However, the northern valley walls are slightly steeper than those at the southern boundary of the valley, which then slopes upward gradually toward the C-b Tract. The Piceance Creek Valley decreases in elevation from east to west in this area, so that nighttime katabatic cold-air drainage flows advect from east to west, or from Trailer 022 to Trailer 020 to Trailer 021.

As mentioned at the outset of this discussion, the terrain will have a large influence on the meteorology of this region. Considering first Trailer 022, at the eastern end of the monitoring network, a nighttime katabatic (valley or down-slope) flow will exert a tremendous influence on this site.

Of the three monitoring locations in the Piceance Creek Valley, this site has the steepest valley walls in its vicinity. As a result, the nighttime katabatic flow is strongest here. That is, the downslope winds are constrained or channelled at this point such that the nighttime drainage winds often reach 15 miles per hour. In addition, the channelling effects of the Piceance Creek Valley walls normally cause surface winds to flow from one of two preferred directions. At night, the downslope winds parallel the valley contours, generally coming from 115° (east-southeast, referenced to true north). During the afternoon, or whenever suitable pressure gradient conditions exist, the winds generally come from the west-northwest because of the boundary conditions and channelling caused by the valley. This monitoring location has an elevation of approximately 6450 feet above sea level and is at the mouth of Oldland Gulch.

Trailer 020, midway down the Piceance Creek Valley near the Redd Ranch, at the mouth of Gardenhire Gulch, has an elevation of about 6320 feet above sea level. Once again, the valley walls are steeper to the north of this monitoring location. The Piceance Creek Valley widens a little from Trailer 022 to Trailer 020, so that channelling effects are not quite as great at this location. Nevertheless, a well-developed katabatic-anabatic flow cycle affects this site, with the afternoon anabatic flow being fairly well-developed at this location. The channelling effects of the valley walls cause two preferred surface wind directions, southeast and northwest. However, other wind directions are experienced here, particularly during the transition periods between downslope and upslope flows and during periods when the surface pressure gradient dictates to a large degree the surface wind direction.

Trailer 021, located near the Rock Creek School, has the lowest elevation of the three valley trailers, 6200 feet. At this point, the Piceance Creek Valley widens considerably toward the east, so that nighttime katabatic winds are rather light. Daytime anabatic winds are also rather light. However, northwesterly surface winds caused by pressure gradient forces are occasionally moderate in force because of the slight channeling effects of the valley walls to the north and northwest.

Site 023, where the 200-foot meteorological tower is located, is atop the plateau at an elevation of about 6940 feet above sea level. It is approximately 2.5 miles south of the Piceance Creek Valley. This location is relatively high compared to its surroundings, with the nearest points having elevations greater than 7000 feet being .5 miles to the south of the tower. The tower itself is on the top of a small knoll located between Scandard and Sorghum Gulches. Because of its location and the irregularities of the surrounding terrain, meteorological patterns are varied here.

Wind instrumentation is mounted at four levels of the meteorological tower: 8 feet, 30 feet, 100 feet, and 200 feet. The top level of the tower generally remains in gradient wind flow. That is, the winds at that level are normally generated by synoptic-scale features and are usually separated from terrain features and micrometeorological circulations. Occasionally, a weak anabatic flow influence is experienced. However, such is not the case with the three lowest measurement levels. To varying degrees, these levels are influenced by both the katabatic and anabatic circulation cells. However, when strong pressure gradient forces exist in the region and the synoptic-scale wind flow is strong, all four tower levels will reflect a gradient wind flow, with the winds increasing in strength with increasing height.

Trailer 024 is between the Piceance Creek Valley and the meteorological tower location, about 1 mile south of the valley itself. The elevation of this site is approximately 6740 feet. The terrain slopes downward to the west, north, and east, and slopes upward toward the south, in the direction of the meteorological tower. This site is in a transition zone between the micrometeorological effects which prevail in the valley and those meteorological phenomena affecting the tower site. As a result, the meteorological parameters measured at this location are subject to rather rapid variations. The area is generally affected by a weak katabatic (downslope) flow at night and a weak anabatic (upslope) flow during the afternoon hours. However, gradient wind flows generally take precedence over terrain-induced flows at this location.

The terrain atop the plateau is generally barren and fairly rugged, with a few scattered small trees. The topsoil dries rapidly and is very fine, resulting in blowing dust when dry, windy conditions exist. In the Piceance Creek Valley, the terrain is fairly grassy and flat, with steep valley walls on either side. Surface winds are normally rather light in this valley unless channelling effects occur.

During clear nights with rather light pressure gradient-induced winds, rapid radiational cooling will occur in the region because of the barren nature of the terrain and the generally dry character of the air in this portion of the country. As a result, the diurnal range of temperatures will be extremely large. Because of the katabatic flow in the valley, nighttime temperatures will generally be lower in the valley than on the plateau. During the winter, especially, temperatures in the valley may be 20°F lower than they are on the plateau during the early morning hours. In particular, the drainage effects will be spectacular at Trailer 021, which will often experience

RADIAN CORPORATION

temperatures 10°F cooler than those at the other valley monitoring locations during the early morning hours. This phenomenon results from the pooling of cold air in the area of Trailer 021 because of its relatively low elevation and the light nature of the winds here during the night, which thus inhibits surface mixing and promotes the strengthening of the nighttime ground-based inversion. During periods of strong gradient winds and/or cloudy skies, greater mixing of the air near the surface occurs and meteorological conditions (particularly temperature and humidity) are more uniform throughout the monitoring network (on the plateau and in the valley).

IV. OPERATING TIME ANALYSIS

The amended Oil Shale Lease Environmental Stipulations require monitoring air quality for sulfur dioxide (SO₂), hydrogen sulfide (H₂S), and suspended particulates on a continuous basis (when applicable). In addition, hydrocarbons, oxides of nitrogen and other pollutants will be continuously monitored as deemed necessary by the Area Oil Shale Supervisor. Requirements for meteorological monitoring include wind speed and direction at three levels near the proposed plant site, one monitor at a height of approximately 30 feet, one not less than 100 feet, and one at an intermediate level. Temperature is to be monitored at the 30-foot level and at a level at least 100 feet above the plant site. Humidity is to be monitored at one level, height not specified. All these meteorological parameters are to be monitored at least 95 percent of the time over each lease year.

The lease stipulations in force at the time the air monitoring network for Tract C-b was designed required monitoring at four sites for SO₂, H₂S and particulates; required monitoring for hydrocarbons, oxides of nitrogen and other pollutants as deemed necessary by the mining supervisor; and required monitoring over at least 90 percent of each lease year. In order to meet these requirements for 90 percent monitoring at four stations the network design included a complete spare station to be operated continuously so that even with a failure in one station, four stations would still be monitoring. The met tower was designed to monitor wind speed, wind direction, temperature, and relative humidity at four levels: 200 feet, 100 feet, 30 feet and 8 feet.

Since the lease stipulations have changed since the network was designed, the operating time analysis will be presented as follows.

(1) Air Quality Stations

Downtime will be reported as the number of channel-days in the quarter that each channel in each station was not taking data (Table I), and all five stations will be reported. Calibration time will not be counted as downtime. A particular channel will be marked as down on any day when it collects less than half the available data points for that day.

The three stations along Piceance Creek had electrical power prior to September 1 (020, 021, 022). Station 023 operated on power from a diesel generator from September 4 to October 4. Station 024 operated on power from a diesel generator from September 27 to October 4. Electrical lines were available at 023 and 024 after October 4.

Table II lists air quality data collection percentages for each species for each month and for the quarter. The quarterly average for gaseous species and for all species are also given. For SO_2 , H_2S , and particulates, the percentages were obtained with an effective four station network from the four stations plus one operating spare station (023). For the other species the percentages were obtained with an effective one station network from one station (020), plus one operating spare station (023).

(2) Meteorological Tower

The channels which will be reported in the operating time analysis include wind speed and wind direction at the 200, 100 and 30-foot levels; the temperature at the 200, 100 and 30-foot levels; and the relative humidity at the 200, 100 and 30-foot levels (Table III). Downtime will be reported as the number of channel-days in each quarter that each of the above data

channels were not taking data. A particular data channel will be marked as down on any day when it collects less than half of the available data points for that day. The percent monitoring achieved will be calculated based on wind speed being taken at the 200, 100 and 30-foot levels; wind direction being taken at the 30-foot level and either the 100 or 200-foot level; and relative humidity being taken at the 200, 100 and 30-foot level.

V. METEOROLOGICAL SUMMARY

The period from September through November brought near normal average temperatures and precipitation to the Tract C-b region of western Colorado. Temperatures were mild to warm throughout the first half of the quarter, but became much cooler during the second half of the period, particularly in November. However, such a climatological sequence is normal for the region. Although precipitation totals were near normal for the quarter, the actual amounts received were light (about two and one-half inches), since the area seldom measures more than one inch of precipitation during any one month.

The western Colorado region had basically sunny skies during the September to November quarter. For the entire period under consideration, the area received about 75% of the possible sunshine. The region had a total of 45 clear days, 20 partly cloudy days, and 26 cloudy days. Cloud coverage in the Tract C-b region averaged 4.2 out of a possible 10 for the sunrise to sunset time period and 3.8 out of a possible 10 for the entire quarter. September had an unusually large number of clear days, while October was rather cloudy. November had near normal amounts of cloudiness.

For the quarter, the mean upper flow showed a slight ridging condition through the Intermountain Region and slight troughing over the eastern United States. This ridging was particularly well-developed and persistent during September. The quarter was particularly noteworthy for the large number of upper cyclonic circulations which separated from the main portion of the upper flow and settled over the southwestern United States. As a result, precipitation over New Mexico, Arizona, Texas, and southern portions of Colorado was well above normal during the quarter.

Considering the Tract C-b, the stability wind rose shows that winds on the plateau during the September to November quarter most commonly were southeasterly through south-southwesterly and west-northwesterly to northwesterly. The other frequencies of occurrence of wind direction showed a bias toward the western half of the distribution. Winds from the northeast quadrant were fairly uncommon during the quarter. The strongest winds on the plateau, however, were almost always south-southeasterly to south-southwesterly or northwesterly, preceding and following the passage of a cold front, respectively. Winds in the Piceance Creek Valley, which showed a very strong katabatic-anabatic circulation dependency, were generally much lighter than those winds on the plateau and were generally east-southeasterly or west-northwesterly in direction.

Nighttime temperatures were normally lower in the valley than on the plateau during the quarter because of the strong radiational cooling which prevailed on clear nights with light winds. Therefore, diurnal temperature ranges were much greater in the valley. Trailer 021 normally achieved nighttime minimum temperatures which were considerably colder than temperatures at other monitoring locations when the well-developed radiational cooling conditions existed.

Considering each month separately:

MONTHLY METEOROLOGICAL SUMMARY FOR SEPTEMBER

A. Summary of the Major Features of the
General Circulation Affecting Western
Colorado

The domination of the upper air flow pattern by meridional characteristics which existed during August continued into the month of September over the North American continent. The long-wave circulation alternated between meridional and zonal flow throughout the month, with each regime lasting for a period of about five days. However, the periods of large amplitude in the long-waves were dominant in relation to the mean circulation pattern.

The mean position of the axis of the long-wave trough during September was located through the central part of North America as it was during the month of August. This circulation pattern produced below normal temperatures and above normal precipitation from the Rocky Mountains eastward to the Appalachians. Rainfall was slightly above normal and temperatures were slightly below normal along the Atlantic Coast. Temperatures were above normal and precipitation was below normal in western North America because of the persistence of the upper ridge in that region. However, the southwestern United States was an exception to the generally dry conditions in the west because of a succession of cold-core low pressure areas aloft which cut off from the main flow and settled over Arizona. These cutoff lows in combination with an abundance of moist air at high altitudes off the Pacific Ocean resulted in copious amounts of rainfall in Arizona, New Mexico, and the western half of Texas during September. El Paso, Texas, for instance, had measurable precipitation on 12 days during September, with a total rainfall for the month of 6.68 inches, which is 5.52 inches above normal.

September also produced two powerful hurricanes, Carmen and Fifi. Hurricane Carmen achieved landfall south of New Orleans, Louisiana, during the evening of September 7th. Hurricane Fifi had a landfall near Belize in Central American on September 19th. However Fifi eventually meandered through Central American into the Pacific Ocean, where it regenerated into Pacific Hurricane Orlene. Orlene then tracked northward toward the Baha Peninsula and was eventually partly responsible for the heavy rains in the southwestern United States on September 22nd, 23rd, and 24th, as its moisture became entrained in the subtropical jet stream which traveled over the Pacific Ocean and then over Mexico, New Mexico, and Texas.

Meteorological events on September 1st centered on the meridional flow enveloping North America. A strong blocking ridge was centered off British Columbia, while a large amplitude trough extended from Hudson's Bay to Oregon. A strong cold front, featuring several surface waves, extended on a northwest-southeast line through Colorado. The blocking ridge aloft began to weaken on September 2nd and the entire long-wave trough began to move eastward rapidly as the next long-wave trough in the hemispherical flow pattern dug southeastward at 150° W latitude. The surface continental polar cold front strengthened at this time and pushed westward over the Tract C-b region during the morning, bringing much cooler temperatures to the area.

By September 3rd, the polar front jet stream had weakened considerably and the long-wave trough axis had moved eastward to a position at 90° W latitude. Correspondingly, the long-wave ridge in western North America also weakened considerably. As a result, the plateau region of Colorado had mild, fair weather and light winds with a warming trend beginning to develop in the area.

September 4th featured the weakening of all of the prominent weather systems in North America. The long-wave trough, which was still centered along 90° W, weakened further as did the ridge in the west. Mild, fair weather and light winds continued at Tract C-b because of the subsiding air aloft and the gradually weakening surface pressure gradient. By September 5th, the upper circulation showed definite zonal tendencies. However, a strong short-wave in the northern Rockies was digging through what remained of the long-wave ridge at this time. The maritime polar cold front associated with this short-wave trough moved rapidly through Colorado during the day, cooling temperatures slightly and causing a few showers which were mostly orographic in nature.

On September 6th the short-wave began to dig into the long-wave trough position over central North America after having passed through the ridge position. The 500-millibar flow was basically weak. A weak surface high pressure area was centered over northern Arizona, causing warm temperatures, light winds, and generally fair skies in western Colorado. September 7th brought little change in the meteorological conditions at the Tract C-b. The weak surface high was now centered over central Colorado and ridging aloft was building northward into the state. Skies remained clear and temperatures were warm, much above normal for the time of year. Because of the weak pressure gradient, winds remained light and orographic wind systems (valley and mountain circulations) were well developed.

On September 8th, a weak, zonal 500-millibar flow prevailed over North America with slight ridging over the plateau region. A surface high was again centered in Colorado. Temperatures were well above normal with some orographic showers over the Rocky Mountains to the east; winds were fairly light. September 9th was a continuation of the zonal pattern over North

America. Temperatures were once again well above normal throughout western Colorado. Scattered showers continued to dot the region. A weak surface low began to develop in the vicinity of Grand Junction.

September 10th signaled an end to the zonal flow of the previous few days as a strong short-wave began to dig over the northwestern coast of the United States. The developing surface low of the previous day was stationary over western Colorado and eastern Utah. A strong continental polar cold frontal system began to organize in northern Montana. The extremely hot weather continued over western Colorado, but the showers became more numerous and the surface winds increased in strength as the low deepened.

September 11th saw rapid changes occur in the long-wave pattern. The short-wave continued to dig southward in the western United States, as lee cyclogenesis took place in southeastern Colorado. In conjunction with the digging trough, a long-wave ridge began to build northward upstream around 130° W. The surface low over western Colorado remained intact and was fairly strong (996 millibars). The cold front over the northwestern United States advanced steadily southeastward, passing through the Tract C-b region during the late afternoon. This frontal passage brought showers and thundershowers, a sharp drop in temperatures, and strong winds to the area. By September 12th the upper flow was strongly meridional, with the long-wave ridge continuing to build in the Gulf of Alaska and the long-wave trough amplifying over the plateau states. The cessation of positive vorticity advection over the region during the early morning hours resulted in clear skies during the remainder of the day, but temperatures were nevertheless much lower than those of the preceding day because of the continuing cold air advection. Winds diminished in strength during the day.

On September 13th another short-wave trough dug southward into the long-wave trough position over western North America. However, the short-wave trough had the effect of tilting the mean long-wave trough axis to a southwest-northeast line. Also, the vorticity from this system hung back over Nevada and Utah as the rest of the long-wave moved eastward slightly. The development was the beginning of the first of a series of cold-core cutoff lows over the southwestern United States. Cloudiness and a few showers also returned to western Colorado because of this system. Temperatures on the 13th moderated somewhat from the cool temperatures of the preceding day. Winds were generally light and variable.

By September 14th, a cold low aloft had formed over northeastern Nevada. As a result, cloudiness and showers were widespread over the western half of Colorado and all of Utah. Temperatures were mild and the winds were light and variable. On the 15th of September the 500-millibar low was over northern Arizona. Widespread rains continued over Colorado, as temperatures varied little from those of the 14th and light winds prevailed because of a weak surface pressure gradient.

By September 16th the low aloft had moved northeastward to the vicinity of Grand Junction and had filled slightly. Therefore, the rains and cloudiness decreased somewhat in western Colorado, although showers and thundershowers were still scattered around the region during the afternoon. Temperatures remained mild and winds remained light. On September 17th, the upper ridge which had extended from California to British Columbia during the preceding three days weakened as a short-wave pushed over it and began to drop into the central part of North America. The weak cyclonic circulation aloft remained over the southwestern United States, centered over central Arizona. A few cumulonimbus clouds

were scattered over the area during the afternoon. A warming trend began to effect the region, although winds were still rather light.

On September 18th another strong short-wave pushed through the long-wave ridge and dug into Alberta, Canada. The weak cutoff low circulation retrograded slightly to southwestern Arizona. Temperatures continued their warming trend and cloudiness decreased somewhat over the Tract C-b region. The cutoff remained stationary over Arizona on the 19th, but the upper flow pattern became more meridional as a ridge built northward in the Gulf of Alaska and a strong short-wave trough dug southward just east of the Rockies. Although a small surface low developed in eastern Utah, skies were clear throughout northwestern and west central Colorado. Winds were generally light.

On September 20th the strong meridional flow pattern continued, with a ridge in the Gulf of Alaska and a long-wave trough through central North America. The now strengthening stationary cold low aloft was centered over extreme southwestern Arizona. A cold front eased through the area from the east during the late afternoon but affected temperatures only minimally; the main effects of the front being a drying of the air and a shifting of the winds to a northerly direction. Skies remained clear throughout the day. The low aloft over the southwestern United States drifted southward into Mexico and filled slightly on the 21st and the meridional nature of the upper circulation over North America continued on this day. Western Colorado was clear and warm because of the subsiding air from the upper ridge to the west. Local circulations (anabatic and katabatic flows) were well developed on the 21st.

On September 22nd the cold cutoff low over southwestern Arizona strengthened once again as cold air was advected into it.

Meridional flow continued over North America as the long-wave trough axis progressed eastward to a position through the Ohio River Valley. Meanwhile, the remains of Atlantic Hurricane Fifi, which had slammed into Belize in Central America three days earlier, reorganized into Pacific Hurricane Orlene and moved northward toward the Baja Peninsula. Generally, partly cloudy skies prevailed over western Colorado on this day, with warm temperatures, light winds, and a few showers scattered over the region.

The generally meridional long-wave pattern progressed slightly eastward on September 23rd. The low aloft remained stationary over southwestern Arizona and a small surface low and weak lee trough began to develop over northeastern Colorado. This troughing action shifted the winds to a northwesterly direction during the afternoon, in western Colorado, but the wind speeds remained low. Skies were clear throughout the area except for a few orographic showers and temperatures were mild at the Tract C-b.

Several large-scale changes occurred on September 24th. The cutoff low over Arizona weakened, as did the entire meridional pattern over North America. However, a strong short-wave in the Gulf of Alaska began to work its way through the long-wave ridge off the western coast of Canada. Scattered cloudiness and a few showers returned to western Colorado, but temperatures remained warm. Winds increased in speed somewhat. By September 25th the long-wave pattern became zonal across the United States. However, the strong short-wave continued its southeastward progression through British Columbia. Scattered cloudiness, a few showers, mild temperatures, and generally light winds prevailed over western Colorado.

A zonal flow pattern existed over North American on September 26th. The cold low aloft which had persisted over the southwestern United States for the past twelve days was finally ejected northeastward into Oklahoma by the strong short-wave in the northwest, which had reached the Washington coast. A strong maritime polar cold front organized along the northwestern United States-Canada border. Meteorological conditions in the Tract C-b region changed little from those of the previous day, with partly cloudy skies, scattered afternoon showers, light winds, and mild temperatures in the area.

Rapid changes occurred on September 27th. The strong short-wave dug southward over the west central United States as a strong maritime polar cold front rushed through the Inter-mountain region of the western United States. The cold front passed through the Tract C-b region during the late morning, causing scattered showers, strong northwesterly winds, some blowing dust, and much cooler temperatures. Skies cleared by sunset. By September 28th the short-wave and cold frontal system had continued to move southeastward rapidly and had reached the central section of North America. Surface and upper ridging affected western Colorado, causing freezing temperatures (during the night), clear skies, and diminishing northwesterly winds.

A broad long-wave troughing pattern enveloped North American on September 29th with several strong short-waves entrenched in the flow. The jet stream and its baroclinicity retreated northward to a Montana-South Dakota line. Subsiding air continued to affect western Colorado, causing clear skies, moderating temperatures, light winds, and extremely dry conditions. The long-wave pattern became more zonal on September 30th as fast polar jet stream westerlies affected the northern sections of the United States. Meteorological conditions in the Tract C-b area changed

little from those of the previous day, with continuing clear skies, light winds, mild temperatures, and very dry air.

B. Micrometeorology of the Tract C-b Region

The Piceance Creek Basin is subject to local circulations (anabatic and katabatic winds) of varying intensities throughout the year. These flows are best organized when clear skies and a weak pressure gradient prevail over the area, conditions which are rather common in western Colorado. During the night the higher elevations cool more rapidly than the valley floor, causing cold, dense air to collect and flow toward lower elevations. During the day the opposite effect occurs, in that the higher elevations receive more direct insolation earlier in the day, causing them to warm more rapidly. The resultant density difference between the valley tops and valley floor causes an anabatic flow, with winds blowing up the valley floor and walls.

Considering the Piceance Creek Basin and the three monitoring trailers located in this valley, the valley-mountain flow regime is very evident. Trailer 022 has the most eastern location of the three trailers in this valley and has the highest elevation above mean sea level. Trailer 021 is located at the western end of the valley and has the lowest elevation above mean sea level. Trailer 020 is intermediate in both location and elevation. These location and elevation differences cause micrometeorological effects to appear in the data as a result of the dominant anabatic-katabatic flow regime in the valley.

For instance, considering the diurnal variations of wind speeds at these three trailers, winds are strongest (6 mph) on the average at Trailer 022 which has the highest elevation. Winds were

lightest on the average during September at Trailer 021, which is at the lower end of the valley. The diurnal wind speed distribution for these three trailers indicates that the katabatic (downslope) wind is strongest at Trailer 022 and weakest at Trailer 021. Conversely, the anabatic (upslope) wind is most strongly developed at Trailer 020 and equal in intensity at the other two trailers. That is, nighttime winds are strongest at Trailer 022 and weakest at Trailer 021. Daytime winds are strongest at Trailer 020.

These winds have a profound influence on the temperatures experienced in all three locations. Trailer 022 has the highest mean temperatures. It is warmest at night because radiational cooling is inhibited by the relatively strong winds. Conversely, Trailer 021 has the lowest mean temperatures. This is because nighttime winds are lightest at this location, allowing excellent radiational cooling. Also, cool air from the eastern portions of the Piceance Creek valley drains into this area and settles, causing colder nighttime readings. Moreover, daytime high temperatures are highest at Trailer 022 and lowest at Trailer 021. Temperatures in the valley during September generally averaged 53.5°F , with an average maximum temperature of 71°F and an average minimum of 37°F . The highest maximum temperature for September was 93°F at Trailer 020 on the 9th and the minimum was 14°F for the 30th at Trailer 021.

Relative humidities during September averaged 50% in the valley. On a diurnal basis the average maximum relative humidity values of 75% occurred at 0800 hours. The average minimum values, about 28%, occurred at 1800 hours. The highest mean humidities occurred at Trailer 022 and the lowest mean humidities were at Trailer 021. Humidities of less than 15% were common at Trailer 021 during the last half of September.

The existence of a local circulation cell in this valley (anabatic-katabatic) is evident upon inspection of the wind direction data. Winds are generally east-southeasterly at all valley trailers during the night when the katabatic flow dominates and west-northwesterly during the day when the anabatic circulation takes effect. On days during September with well developed upslope-downslope flow characteristics winds were easterly (90° to 110°) and downslope during the nighttime period from 1900 hours to 800 hours. The winds then went through a transition period for the next two hours, backing into the north and then into the west-northwest (300°) by 1000 hours. These anabatic winds usually prevailed until approximately 1800 hours, at which time they would abruptly veer to a northerly direction and then settle into an easterly direction, usually by 1900 hours, as the katabatic flow again took over.

Conditions at the Tract C-b itself, up on the plateau, were somewhat different. In particular, the anabatic-katabatic circulation cell is not as well developed on the plateau. Also, the cooler air generally drains into the valley from the plateau, causing two main effects: (1) the depth of the ground-based radiation inversion is rather shallow (averaging slightly more than 100 feet in depth during September), and (2) temperatures at night are not as low during radiational cooling nights as they are in the valley.

Because the upslope-downslope flow does not effect the tract to the extent that it does the valley, wind directions on the plateau have a high frequency from the southwestern quadrant, in connection with the geostrophic flow (large-scale flow related to pressure gradients). In particular, the 200-foot level of the tower has a very high frequency of southwesterly winds, even at night when the lower tower levels are enveloped by a ground-based radiation inversion and drainage flow.

Winds can be rather strong on the plateau and around the tower site. The highest hourly average wind speed recorded during September was 24 miles per hour on September 27th, as a strong cold front passed the area. Winds increased in speed with height during September, as was to be expected. The average wind speed at the 100-foot level for the month was 9 mph, higher than in the valley.

The air was much drier on the plateau than in the valley (moisture occasionally becomes trapped in the valleys) during September. Humidities for the month averaged in the low 30's.

Mean temperatures for the month of September were slightly higher on the plateau than the valley. Daytime temperatures averaged about 2 degrees lower at the tower site than in the valley, but nighttime temperatures were about 5°F higher, with an average minimum temperature of 42°F and an average maximum of 69°F. The average temperature at 200 feet was 55°F, but the diurnal range of temperatures was smaller than at the lower tower levels.

MONTHLY METEOROLOGICAL SUMMARY FOR OCTOBER

A. Summary of the Major Features of the Upper Flow Over North America

North America during October alternated between periods of zonal and meridional flow, with two sequences of split upper level flow. The upper flow was basically zonal (or west-east) over the United States on October 1, 4, 7, 12, 13, 22, 23, and 24. The flow was generally meridional (north-south) on October 2-3, 5-6, 9, 14-21, and 25-26. Split upper level flow prevailed on October 8, 10-11, and 27-31. The net results of these circulation patterns for the month of October were: much below normal temperatures and below normal precipitation over the north-eastern United States; below normal temperatures and much below normal precipitation over the Atlantic seaboard states; near normal temperatures and precipitation over the Central United States; below normal temperatures and slightly below normal precipitation in the South; much below normal temperatures and below normal precipitation in the north central United States; below normal temperatures and above normal precipitation in the South-western United States; slightly above normal temperatures and near normal precipitation in the Rocky Mountain regions; and generally above normal temperatures and below normal precipitation in the West.

October began with a mean long wave ridge axis extending from western Canada to northern California. A rather deep long wave trough was positioned through the eastern United States. Precipitation was confined to the far northeastern portion of the United States. A stationary cold front extended from Montana through Wyoming to southern Nebraska. By October 2nd, the long wave pattern had amplified so that a well defined long wave trough

extended from the Great Lakes to Florida. A strong upper ridge extended from Utah to north central Canada and a deepening upper trough was approaching the Pacific coast. A weak upper low was off the California coast. On the surface, a large, cold high pressure system was centered over Illinois. A warm front extended southward along the Rocky Mountains from Canada, while a strong maritime polar cold front came inland along the Washington coast. Precipitation was confined to California, Washington, and the northeastern United States.

On October 3rd, all of the major features of the circulation over North America moved eastward. The long wave trough along the Atlantic seaboard moved eastward slightly and amplified. The upper ridge also moved eastward to a position from Kansas to Minnesota and then northward into Canada. The upper trough in western North America also moved eastward and flattened somewhat. On the surface, the large surface high was still centered near the Great Lakes region, while a cold front advanced across the Great Basin. Precipitation was widespread across the Intermountain Region.

By October 4th, the cold front had pushed completely through Colorado into the Midwest. The large surface high moved southeastward to a position along the Atlantic seaboard. At upper levels, strong short waves were located off the coast of the eastern United States, along the Rocky Mountains, and along the west coast. Precipitation, mostly light, was scattered throughout the western two-thirds of the United States. On October 5th, the general positioning of circulation systems remained about the same. The long wave in the western United States amplified slightly. Precipitation was moderate from the Great Lakes to Montana and south from there to Kansas.

On October 6th, the northern half of the long wave which had been over the western United States was reinforced and moved

eastward, thus causing the southern half of this wave to be sheared off, forming a cutoff low aloft over California. The cold front which had been across the Midwest was reinforced by the deepening of the northern half of the short wave and moved southward as a result. Cloudiness and precipitation were widespread in a band from Arizona and New Mexico to Minnesota and the Great Lakes on the 6th, but decreased throughout western Colorado.

By October 7th, the western two-thirds of the nation was under the influence of a large dome of high pressure. The short wave that had been over the Midwest on the 6th moved eastward rapidly, to a position over the Great Lakes. The cold front associated with this short wave extended southwestward from Maine through Tennessee to central Texas. The low aloft over California persisted, causing precipitation over southern California and Nevada. Precipitation also extended along the front from Texas to New York. Skies were clear to partly cloudy over western Colorado. The upper flow pattern was split in the western United States on October 8th, as the upper low persisted. The cold front and short wave in the eastern United States continued to push eastward to a position off the coast. Most of the nation was under the influence of a large, weak high pressure system. Precipitation was confined to California and Nevada.

By October 9th, a short wave approaching the western coast of the United States caused the upper low to be ejected northeastward to a position over Nevada. A weak cold front extended from the Great Lakes to Nebraska but no other significant weather systems affected the United States. Temperatures were cool in the Northeast but seasonable elsewhere. A weak surface high pressure area affected most of the United States, resulting in many areas of light winds and stagnation. Precipitation in the United States was confined to the Great Basin area. October 10th

saw a split upper level flow regime return to the western United States. A short wave trough was located from Idaho to southern California. Showers and a few thundershowers were scattered throughout the Intermountain Region and the western slopes of the Rockies. A few showers fell in the Tract C-b area.

The split flow regime continued in the western United States on October 11th. The short wave from Idaho to California stayed nearly stationary. A cold front extended southwestward from a low pressure system on the Minnesota-Canada border through Nebraska to northern New Mexico. A secondary cold front extended westward to Montana, also from this low. Precipitation was widespread throughout the western half of the nation on the 11th, with showers and thundershowers again dotting western Colorado. By October 12th, the two cold fronts through the northern Plains States had organized into one strong frontal system which extended from the Great Lakes southwestward to the Texas Panhandle. The short wave trough which had been stationary over the western United States for the two previous days finally formed a weak low pressure circulation aloft over western Arizona. Precipitation covered a large portion of the United States extending from Arizona northeastward in a broad band to the Great Lakes region. A large cold high pressure system dominated the weather in the western half of the United States behind the cold front. Considerable cloudiness and a few showers persisted in western portions of Colorado.

By October 13th, another in a series of upper level short waves moving rapidly into the northwestern United States from British Columbia caused the upper low center over the southwestern United States to move slowly eastward. This approaching short wave had associated with it a moderate polar maritime cold front, which was located across central North Dakota and Montana on the morning

of the 13th. Precipitation was widespread across the middle of the United States on the 13th, extending from New Mexico to the Great Lakes in a very broad, nearly solid band. Skies cleared over western Colorado on the 13th as the upper low was forced eastward.

The short wave amplified rapidly on the 14th, causing the cold front to move southward rapidly. The front passed through western Colorado during the morning of the 14th, causing cooler temperatures and a continuance of clear skies. Precipitation once again occurred in a broad band across the central part of the United States because of the strong short wave and cold front. The short wave and cold front continued to move eastward rapidly on October 15th, thus forcing the precipitation area eastward with it. A large upper ridge and surface high covered the western half of the United States on the 15th, thus causing a continuance of fair, dry conditions in western Colorado on this day.

October 16th and 17th were very similar with regard to the upper flow patterns which prevailed over North America on these two days. A large surface high pressure cell dominated most of the United States during the period. Precipitation was confined to the eastern fourth of the country. A large upper ridge prevailed over California, Nevada, Utah, Idaho, Wyoming, and Colorado on these two days, while a large amplitude upper trough extended from the Great Lakes region to the Gulf of Mexico. Fair and mild weather prevailed over western Colorado on these days.

The same basic meridional flow pattern persisted over the United States on October 18th and 19th. A strong upper ridge dominated the flow in the western United States on both days, with a deep upper trough along the Atlantic seaboard. The systems progressed eastward very slowly, so that another long wave trough

began to approach the Pacific northwest by October 19th. Precipitation was minimal across the United States on both the 18th and 19th. A weak cold front progressed southward through the eastern half of the nation on the 18th and 19th, but did not affect Colorado at all. Meteorological conditions remained fair and unseasonably warm throughout western Colorado on both of these days.

The upper flow began to change on October 20th. The upper ridge and trough progressed eastward slowly, but a strong short wave began to dig southward along the west coast of the United States. A cold front associated with the short wave extended southward from eastern Washington into northwestern Nevada and northern California. Precipitation was confined to the northwestern and northeastern portions of the United States. Fair and warm conditions continued in western Colorado.

The short wave in the Northwest continued its easterly movement on October 21st, forming a closed upper low circulation in the process. The polar maritime cold front continued its eastward movement, passing through western Colorado during the afternoon of the 21st. Because of the upper low and its associated moisture and positive vorticity advection, cloudiness and scattered rainfall returned to western Colorado on this day. Actually, precipitation was scattered throughout the entire length of the Rockies. Precipitation and considerable cloudiness continued in western Colorado on October 22nd as the upper low strengthened slightly and remained stationary over northern Nevada and northern Utah. The upper flow became fairly zonal on this day, with the jet stream located along the United States-Canada border. The polar maritime cold front moved eastward through the northern Plains States but did not advance southward because of the zonal nature of the upper flow, the northern position of the jet stream,

and a blocking high pressure cell in the southeastern United States. Precipitation was widespread throughout the southwestern United States on this day.

The upper level flow over northern Nevada strengthened further by the morning of October 23rd, causing the broad area of precipitation to persist over the Plateau region and southwestern United States. Temperatures were cooler and cloudiness and precipitation were widespread throughout western Colorado on this day. The zonal character of the upper level flow and the northward retreat of the polar front jet stream into Canada caused the maritime polar cold front through the central part of the United States to become stationary. Precipitation was scattered along this front from Texas to New York. Rains continued in western Colorado during the morning of the 24th but began to diminish in areal coverage later in the day as the upper low over northern Nevada began to fill gradually. A short wave moving south from Canada into the northern Great Plains brought with it a weak cold front which extended into northern Wyoming during the morning. Precipitation was heavy in Texas and Oklahoma on this day. Clearing took place in western Colorado during the night of the 24th as the cold front passed through the region and a high pressure ridge built southward into the area.

The upper flow once again had meridional characteristics by October 25th, although the flow was beginning to show splitting tendencies once again in the western United States. An upper ridge extended northward from Colorado through Montana and into Alberta, Canada. A long wave trough extended southeastward from Hudson's Bay into New England and a short wave and upper closed low came onshore in the Pacific northwest. Precipitation occurred in Washington and Oregon and through the center of the nation, along a cold front which extended from Texas to the Great Lakes. Mild temperatures and clear skies prevailed in western Colorado.

Cloudiness returned to western Colorado as the short wave moved eastward from the Pacific coast on the 26th. Precipitation was restricted to the Pacific Northwest, the Southwest, and the Midwest as an upper ridge which extended from Florida to Alberta, Canada brought fair weather to most of the nation. The upper flow became split in the southwestern United States on the 27th, as a cold pool of air at upper levels became cutoff from the longwave circulation and formed a closed low over western Arizona. This low caused scattered light precipitation throughout the Southwest on this day. Cloudiness increased throughout western Colorado as the day progressed and light precipitation was experienced in the area during the evening hours.

- An approaching short wave from the Pacific caused this upper low to be ejected northeastward by October 28th, resulting in continued cloudiness and scattered precipitation in western Colorado. This approaching short wave caused the generation of a strong surface low pressure area (cyclogenesis) in Oregon, from which trailed a polar maritime cold front into California. The split flow characteristics and broad upper level troughing which prevailed in the western two-thirds of the United States caused this entire region of the nation to be covered by cloudiness and precipitation.

The split flow in the polar front jet stream continued on October 29th, with a strong upper low forming over Nevada. A strong surface low was centered over western Utah during the morning of the 29th, with a moderately strong maritime polar cold front trailing southward. Cloudiness and precipitation continued in western Colorado, as the storm produced the first widespread snow of the season in the Intermountain Region. These cloudy and snowy conditions persisted in western Colorado on October 30th, as the upper low intensified and moved northeastward to a position

over central Utah. The surface low had meanwhile moved to eastern Colorado and weakened somewhat. Cold frontal passage occurred late on the 29th in western Colorado. By the morning of the 30th, it was located on a line from eastern Colorado southward to western Texas. Much of the nation received precipitation on this day due to the amplitude of the upper level troughing over the western United States.

Cloudiness and snows continued in western Colorado on October 31st as the intensifying upper low was pushed northeastward by an approaching short wave just off the northwestern coast of the United States. On the morning of the 31st, this upper low was located over central Wyoming. The split in the upper flow over the western United States continued, however, with a broad upper trough continuing to affect the western two-thirds of the United States. A surface low was located in Wyoming by the morning of the 31st, while a maritime polar cold front extended from Idaho into central California. Precipitation was widespread throughout the western and central portions of the nation.

B. Summary of Meteorological Conditions in the Tract C-b Region

Precipitation totals and temperatures were near normal in the Tract C-b region of western Colorado during the month of October. The area experienced seven cold frontal passages during the month (October 3, 5, 10, 14, 21, 24, and 29). The strongest of these fronts was the one which passed through the region on October 29th. Precipitation was experienced in the area on twelve days of October (October 3, 5, 10, 11, 22, 23, 24, 27, 28, 29, 30, 31), but most of the daily totals were low. Snow was experienced in the area of the Tract C-b on October 29th, 30th, and 31st, but

snow amounts were rather light and melting occurred within a few days. Temperatures were below normal during the periods from October 3rd through the 7th and October 11th through the 15th. Temperatures were much below normal on October 29th, 30th, and 31st. Temperatures were above normal on the other days of the month, but were much above normal during the period from October 17th through the 22nd.

The area received 62 percent of the possible sunshine during the month. Sky coverage by cloudiness in the general area totalled 5.3 out of a possible 10 during the period from sunrise to sunset during October, and 4.9 out of a possible 10 for all possible observations during the month. The region experienced 10 clear days, 9 partly cloudy days, and 12 cloudy days during October. Thunderstorms were in the area on two October days (October 10th and 11th). Grand Junction, Colorado, about 75 miles to the southwest of the Tract C-b, received .72 inch of precipitation during October, which is .21 inch below normal for the month.

Poor dispersion or air stagnation conditions occurred occasionally in western Colorado during October. The period during which dispersion conditions were worst in the Tract C-b region was from October 17th through the 20th. During this interval, the region was influenced by a large persistent upper ridge over the western portions of the United States. This ridge brought clear skies to the Tract C-b area but also brought rather low mixing heights and subsidence aloft. The weak surface anticyclone associated with this upper ridge further compounded the problem by causing very light surface winds throughout the area. The net result was an extended (3 or 4 days) period of locally poor dispersion conditions.

The following is a summary of all air stagnation messages from the National Weather Service pertaining to western Colorado

during the month of October. The messages were received in Radian's facilities via the Service "C" Weather Teletype Circuit from the National Weather Service, a cable service to which Radian subscribes. These Air Stagnation Narratives are coded as "FKUS" messages.

- October 2nd: "In the western United States, the ridge moving through the Intermountain Regions of the Rockies is supporting the development of stagnation in portions of Colorado, Arizona, New Mexico, and West Texas...The stagnation will diminish as the ridge moves eastward."
- October 9th: "The stagnation through the Rockies this morning will diminish during the day as the trough moves into the Intermountain Region."
- October 16th: "Deteriorating local dispersion conditions over much of the United States west of the Rockies during the next 24 hours."
- October 17th: "Stagnation conditions are persisting over the western and southwestern United States as a result of little movement of the upper ridge over the Pacific Northwest and no movement of the flat surface high pressure area."

- October 19th: "Large-scale stagnation exists over the western United States from extreme West Texas through New Mexico to western Montana. An ASA (Air Stagnation Advisory) is in affect for much of this area."

C. Meteorological Discussion of Tract C-b and the Piceance Creek Valley

Meteorological conditions often varied considerably from the Piceance Creek Valley to the Tract C-b itself during the month of October. Anabatic and katabatic circulations were much better organized in the valley at Trailers 020, 021, and 022 than on the plateau at Trailers 023 and 024. Nighttime temperatures were much colder in the valley than on the plateau during nights when radiational cooling occurred and the downslope flow became organized. The diurnal range of temperatures was much greater at the Valley Trailers (020, 021, and 022) because of the mountain and valley circulations, with daily temperature ranges of 35° common at these trailers during October.

Trailer 021 generally had the largest diurnal range of temperature, mostly because of its location. At this location, the katabatic winds were fairly light at night because of the widening of the valley just upstream to the southeast. As a result, the mixing of the air was diminished during the night and cold air from higher elevations was allowed to collect in this relatively low area of the valley. Thus, radiational cooling was allowed to proceed uninhibited and temperatures fell rapidly during the night. Nighttime minimum temperatures were generally at least 5°F colder at this trailer than at the other two trailers in the valley and at least 10°F colder than minimum temperatures at Trailer 023 on the plateau, where the katabatic circulation cell was not developed so as to abet rapid cooling.

On the majority of the nights in October, Trailer 021 had the lowest minimum temperatures, followed by 020, 022, and 023. Temperatures were higher at Trailers 020 and 022 during the night because of increased wind speeds from the katabatic circulation, which mixed the air near the surface to the extent that the ground-based radiation inversions that formed near these trailers were not so intense as the inversion (coldest at the lowest level) at Trailer 021. During the afternoons, temperatures were much more uniform at all trailers because of increased vertical mixing from convection and the anabatic (upslope) flow. Daytime maximum temperatures during October were generally highest at Trailer 023, followed closely by Trailers 022, 021, and 020, in that order.

Relative humidities were generally rather uniform in the Piceance Creek Valley during the month, averaging about 62 percent. Humidities were a little lower on the plateau (because of slightly drier air and higher average temperatures), averaging about 53 percent at the 30-foot level of the meteorological tower.

Winds were generally much lower in the valley than on the plateau during the month. Winds generated by pressure gradient forces were normally decreased in strength substantially from the plateau to the valley. While the strongest winds during the month were generally the result of synoptic-scale developments on the plateau at the meteorological tower, the strongest winds in the valley were often the result of katabatic or anabatic circulations.

Winds at Trailers 020, 021, and 022 exhibited marked channelling effects because of the steep valley walls in the vicinity. Winds at Trailer 022 were normally either east-southeast or west-northwest while winds at Trailers 021 and 020 were normally either northwesterly or southeasterly because of the katabatic-anabatic circulation cycle. However, during transition periods

between upslope and downslope flow, or vice versa, the wind direction was rather variable at these locations. In addition, on occasions when the surface pressure gradient was weak and an anabatic or katabatic circulation cell was not developed, the winds were often calm or variable in direction.

At Trailer 023, winds did not exhibit as much of a terrain or micrometeorological dependence. Pressure gradient forces for the most part controlled the wind directions and speeds at the meteorological tower. Both the mode and mean of the distribution of wind directions at the tower were south-southwesterly or southwesterly, depending on the level of the tower under consideration, which is a reflection of the pressure gradient forces which existed in the Tract C-b region during October. Winds generally veered in direction (clockwise progression) and increased in speed with increasing height at the meteorological tower.

Average temperatures in the monitoring network for the month of October ranged from 39.4°F at Trailer 021 in the valley to 47.3°F at the 30-foot level of the meteorological tower at Trailer 023. The average temperature at Trailer 020 was 41.3°F , two degrees higher than at Trailer 021. At the meteorological tower, average temperatures were fairly uniform, ranging from 45.7°F at the 8-foot level to 47.3°F at the 30-foot level, with the 100-foot and 200-foot levels registering intermediate values. However, the average temperatures do not reflect the diurnal variation of vertical temperature structure which occurred at the tower. During cloudy, wet days, near-isothermal conditions prevailed at the four tower levels. However, on clear or partly cloudy days, the normal thermal pattern was: (1) inversion to 100 feet, with unstable lapse rates above that during the night, and (2) unstable lapse rates to 100 feet with an inversion above that during the day. The layer above 100 feet seems to have been

decoupled from the layer below that level much of the time. However, during extremely windy or cloudy conditions, there was more uniformity in the vertical temperature structure.

The highest daily average humidity reading in the valley during October was 93.9 percent at Trailer 022 on October 29th. October 5th also had average relative humidities above 80 percent. Likewise, on the plateau, October 5th and 29th had the highest average relative humidities. October 1st and 2nd were the driest days of the month, both in the valley and on the plateau, with daily average humidities in the twenties.

The highest daily average temperature in the region for October occurred on October 1st. The average temperature this day at the 30-foot level of the meteorological tower was 61.0°F. Meanwhile, in the valley, the average temperatures ranged from 46.0°F to 48.1°F. The much lower average temperatures in the valley were due to much lower temperatures from strong radiational cooling during the night. The lowest daily average temperatures in the network during October were recorded on October 30th, a snowy day, when temperatures ranged from 27.6°F to 29.9°F in the valley and from 29.8°F to 31.0°F at the four meteorological tower levels. The highest maximum temperature recorded in the valley during October was 73°F at Trailers 020 and 021 on October 2nd. The highest temperatures recorded at the meteorological tower during the month occurred on October 1st, 2nd, and 15th. The lowest temperature recorded in the valley during October was 14°F at Trailer 021 on October 15th. The lowest temperature recorded on the plateau was 24°F on October 30th.

Considering the valley stations, winds were strongest at Trailer 022 during the month, averaging 5 miles per hour. Winds at Trailer 021 averaged 3 miles per hour and winds at Trailer 020

averaged 2 miles per hour. The highest daily average winds occurred on October 3rd and 21st. On a diurnal basis, the strongest winds occurred from 1300 to 1500 hours at Trailer 020, from 1500 to 1800 hours at Trailer 021, and from 0100 hours to 0200 hours (katabatic winds) at Trailer 022.

At the meteorological tower, wind speeds averaged 2 miles per hour for the month at the 8-foot level, 7 miles per hour at the 30-foot level, 6 miles per hour at the 100-foot level, and 9 miles per hour at the 200-foot level. The windiest days of the month on the plateau were October 21st and 31st. On a diurnal basis, winds were strongest on the plateau during the period from 1300 to 1500 hours. Winds were lightest from 0800 to 0900 hours. The highest 5-minute average wind speed recorded in the valley during October was 23 miles per hour at Trailer 021 on October 3rd. The highest 5-minute average wind speed recorded at the meteorological tower site during October was 35 miles per hour, at the 100-foot level, on October 21st.

MONTHLY METEOROLOGICAL SUMMARY FOR NOVEMBERA. Summary of the Major Features of the
General Circulation over North America

During the month of November, the general circulation over the United States was fairly normal. That is, in general, the various sections of the country did not experience prolonged periods of abnormally extreme cold or heat. In addition, most sections of the nation did not deviate appreciably from monthly precipitation norms. The long wave circulation in the upper atmosphere generally alternated between periods of zonal and meridional flow during the month. Split flow dominated the upper flow from November 1st through November 6th. Otherwise, meridional or zonal flow regimes prevailed. Zonal flow, or west-to-east flow which promotes rapid variations of a rather weak nature in the meteorological conditions in a region, occurred in the United States from November 7th through the 9th, the 16th through the 23rd, and on November 30th. Meridional flow, or north-south flow which causes rather extreme meteorological conditions (hot or cold, depending on relative location in the circulation pattern) of a rather persistent nature, existed from November 10th through the 15th and from November 24th through the 29th.

The results of these circulation patterns over the various sections of the country during November were fairly uniform. In general, much of the nation had temperatures which were above normal for the month and monthly precipitation totals which were also slightly above normal. Specifically, the north central portion of the country, including the upper Midwest and Ohio Valley, had temperatures and monthly precipitation totals which were slightly above normal. The Northeast had near normal temperatures but below normal precipitation. The Atlantic seaboard region had temperatures and

precipitation totals which were slightly above normal for the month, while the South had near normal temperatures and slightly above normal precipitation. The central portion of the United States had above normal temperatures and slightly above normal precipitation during the month. Meanwhile, the Rocky Mountain region and Intermountain Region had slightly below normal temperatures and precipitation totals which were slightly above normal. The Southwest also had temperatures which averaged slightly below normal, but had above average precipitation. Finally, the West and Pacific coast areas had temperatures which were much higher than monthly normals and precipitation totals which were above normal.

No extremely cold Arctic air masses advected south of the Canadian border during the month. The mean position of the long wave trough over North America was through the west central United States during November, while a weak mean ridge was situated on a north-south line through the eastern portion of the nation.

November began with a broad upper troughing pattern over the western United States, with ridging over the Atlantic seaboard. The split flow conditions caused one large upper low pressure area over northeastern Wyoming and another over northern California. A stationary front extended from the Great Lakes to southern Texas and a cold front extended southward from a surface low over eastern Nevada. Precipitation was scattered throughout the western half of the nation and also along the stationary front from Texas to Indiana. Skies were overcast in western Colorado in the vicinity of Tract C-b on the 1st and rain and snow showers were widespread throughout the area.

November 2nd was much the same. The upper low in Wyoming moved northeastward to the North Dakota-Canada border and the upper low in the Southwest strengthened slightly and moved southward to southern California. A surface high pressure region began to build (anticyclogenesis) over the western portion of the nation. The stationary front through Texas moved northward as a warm front to a position along the Red River Valley, while the low over Nevada moved to southern Arizona. Precipitation was widespread across the western three-fourths of the nation. Cloudiness decreased somewhat in western Colorado, but scattered rainshowers still persisted in the region.

On November 3rd, the upper low in the Southwest moved to northwestern Arizona and filled slightly. Meanwhile, an upper ridge began to build into the Pacific Northwest. A stationary front extended from the Great Lakes to southwestern Texas. Precipitation, much of it heavy, covered the entire midsection of the country. High pressure continued to build into the western portion of the nation. Colder air advected into western Colorado, with rain, snow, and fog persisting throughout the area of the Tract C-b during the day.

The split flow regime continued on November 4th, as the upper ridge in the Northwest continued to strengthen. Weak upper lows were centered over western Kansas and western Utah. A cold front extended from New York to a low over Arkansas and then southwestward to southern Texas. Precipitation was heavy in a broad band from southern Texas northeastward to the Great Lakes, with many precipitation totals exceeding one inch. Western Colorado continued under a moderate high pressure regime at the surface, although a very weak surface low was centered over southeastern Utah. Middle cloudiness and a few light showers were scattered throughout the area of the Tract C-b.

The split flow pattern began to break somewhat by November 5th. A strong upper low was centered over Iowa and a very weak upper low was over southwestern Utah. An upper ridge extended from Oregon to Montana. A strong long wave trough began to deepen at about 150°W longitude. At the surface, a weak cold front extended southward from a low pressure center over the Great Lakes to Alabama and then into the Gulf of Mexico. An occluded front made its way onto the Washington coast. Precipitation was confined to the eastern third of the nation and to the Pacific Northwest. Weak high pressure at the surface covered the eastern two-thirds of the country. Skies cleared in western Colorado with only a few scattered middle clouds dotting the sky.

November 6th marked the end of the split flow regime over the western portion of the United States as zonal flow began to establish itself. Upper lows were centered over Illinois and the Arizona-Utah border, while an upper ridge extended from Nebraska to Minnesota. Precipitation occurred in Texas, along the Gulf Coast, in the Northeast, and in the Pacific Northwest. On the surface, the cold front moved off the Atlantic coast, while the occlusion in the Northwest remained essentially stationary. A weak surface high centered in Kansas dominated the circulation throughout the nation. Generally fair weather prevailed in western Colorado, with some scattered middle cloudiness in the area during the morning.

A zonal circulation prevailed on November 7th, with a strong upper low in the East and a weak upper cyclonic circulation centered in southern Colorado. A weak upper ridge extended northward from Mississippi to Wisconsin. A short wave moved onto the Pacific coast. A large weak anticyclone

was over eastern Missouri at the surface. A maritime polar cold front extended through Washington and a weak continental polar front dropped southward into Montana. Precipitation was widespread in the Pacific Northwest, Texas and its adjoining states, and in the Great Lakes region. Skies were clear in western Colorado, with a very small high pressure cell centered over central Colorado.

By November 8th, an upper level short wave had advanced rapidly eastward to an Idaho-southern California line. Upper lows were located over Missouri and off the Atlantic seaboard. A cold front extended southward from a low in Alberta, Canada, to Nevada. Precipitation was widespread throughout the Gulf coast states, Texas, and the Intermountain Region. The cold front passed through the Tract C-b region around noon. Cloudiness increased during the day and a steady rain began to fall during the evening.

The short wave moved eastward and dug southward on November 9th as the upper circulation began to exhibit some meridional flow characteristics. An upper ridge extended from southeast Texas to an upper high over the Great Lakes, while the upper trough was located on a Montana-Arizona axis. A cold front extended through the northern Plains states and another weak maritime polar cold front came onshore in Washington. Weak high pressure dominated the eastern half of the nation. Precipitation occurred in Florida, the Pacific Northwest, and over a large section of the nation's midsection extending from Texas to Minnesota and from eastern Utah to Missouri. Cloudiness covered western Colorado during most of the 9th and light rain fell during the morning hours.

The upper flow became meridional by November 10th, as the long wave trough dug southward along a Montana-west

Texas axis. Long wave ridges were located along the Pacific and Atlantic coasts of the United States. The cold front continued its eastern advance through the Midwest, extending along a Minnesota-Central Texas line during the morning. The cold front in the Northwest began to undergo frontolysis (decay) because of decreasing upper level support. A warm front moved northward from the Gulf of Mexico into southeastern Texas. Precipitation was scattered through the Pacific Northwest and the Intermountain Region. Precipitation was also concentrated along the cold front in a broad band from Texas to the western Great Lakes. In western Colorado, skies were overcast during the morning and some snow flurries occurred, but skies began to break by the afternoon as high pressure built into the area.

The meridional pattern amplified on the 11th, with a major trough through the center of the United States and strong upper ridges in the West and East. A strong cold front extended southward from a low over the western Great Lakes region through the Mississippi Valley to a low in southern Alabama, from which a cold front extended southward into the Gulf of Mexico. Precipitation extended northward along this front in a rather wide band. A large high pressure cell dominated the western half of the nation, bringing clear skies and light winds. Western Colorado likewise had clear skies and mild temperatures on this day.

This meridional pattern changed little on November 12th. The long wave trough and western ridge retained their amplitude and moved eastward slowly. High pressure continued to dominate the western two-thirds of the country and precipitation was confined to the Atlantic seaboard, Great Lakes, and Ohio Valley regions. However, a strong short wave began to dig southeastward through the upper ridge in British Columbia, portending a strong continental polar outbreak.

Skies were generally fair (high cloudiness) and temperatures were mild in the Tract C-b region.

The meridional long wave pattern amplified on the 13th as the short wave dug southeastward swiftly on the upstream side of the trough. Cold continental polar air streamed southward down the lee side of the Rockies behind a cold front extending from a low in Kansas to Colorado and then northwestward to Washington. Precipitation covered the northern portions of the country. The cold front passed through the Tract C-b region during the afternoon, lowering temperatures slightly. Skies remained fair.

The meridional pattern continued on November 14th, although the amplitude of the circulation was somewhat reduced. An upper ridge dominated the West while a major trough covered the eastern half of the nation with cloudiness and precipitation. The continental polar cold front continued its southward march, pushing into the Atlantic Ocean and Gulf of Mexico by nightfall. A weak maritime polar cold front moved into the Pacific Northwest. The moderate continental polar cold front retreated eastward out of the Tract C-b region during the day. Broken middle and high cloudiness advected over the area throughout the day. Temperatures were mild.

The meridional circulation pattern of the five preceding days began a transformation into a zonal flow on the 15th, as the ridge in the West flattened and the eastern trough began to lose amplitude. A weak cool front extended westward from a small low pressure center in Wyoming. High pressure covered most of the nation. Precipitation was confined to the Northeast. Middle and high cloudiness covered western Colorado as mild temperatures continued in that region.

Zonal flow re-established itself over the United States on November 16th. A short wave, located on a Minnesota-New Mexico axis during the morning, moved through the center of the nation, causing widespread precipitation throughout the western half of the country. High pressure and light winds covered most of the country. Mild, fair weather prevailed in the vicinity of Tract C-b.

Zonal flow continued on the 17th as numerous short waves progressed eastward across the country. Short waves were located in the Ohio Valley (a rather strong system), Texas, the northern Plains, and the Northwest. A weak continental polar cold front was in the northern Plains and a maritime polar cold front moved eastward onto the Washington coast on this day. Precipitation covered the eastern third of the nation as well as the Pacific Northwest.

The short waves continued their eastward progression on the 18th. The strongest of these waves was located in the Northwest. The weak continental polar cold front in the northern Plains remained fairly stationary, while the maritime polar cold front progressed eastward to a Montana-central California line. Precipitation was scattered through all areas of the country except the Southwest. Cloudiness increased throughout the day in western Colorado. The maritime polar cold front passed through the Tract C-b during the evening, bringing scattered showers and a few thundershowers to the region.

The upper flow became a bit more organized on the 19th, with a long wave trough through the center of the United States and minor ridges along the West and East coasts. The maritime polar cold front extended southward from Minnesota to Kansas and then curved into the Texas Panhandle and New

Mexico. High pressure began to build in the West behind the front. Precipitation occurred throughout the eastern half of the nation, in the Northwest, and in the Intermountain Region. After some snow pellets during the early morning in western Colorado, skies cleared gradually during the day, becoming virtually clear during the evening.

The short wave trough moved eastward to a Minnesota-Louisiana axis by November 20th as an upper ridge built northward over the Intermountain Region. On the surface, a cold front extended southward from a low over the Great Lakes region to Louisiana and then to the southern tip of Texas. A high pressure system, centered in western Colorado, affected the western half of the United States with its circulation. Precipitation amounts were large throughout the eastern third of the country. The Pacific Northwest also had precipitation. Skies were fair in western Colorado, but temperatures were rather cool.

The short wave troughs and ridges continued their eastward progression and by the 21st, short wave troughs were located off the Atlantic and Pacific coasts while a ridge extended northward from Texas to North Dakota. A cold front and low pressure system were located just off the coast of northern California. Precipitation was confined to the Northeast and the West. High pressure dominated most of the nation. The Tract C-b region had mostly fair skies on the 21st, with some scattered to broken middle and high cloudiness over the area.

The zonal upper flow pattern continued its eastward progression on the 22nd, as the Pacific short wave system advanced inland to an Idaho-southern California axis. The maritime polar cold front associated with this short wave

extended from southeastern Montana to southern California by the morning of the 22nd. Another cold front, a continental polar front, dipped into Montana and North Dakota from Canada. Precipitation covered the western third of the nation and the Northeast. Cloudiness increased throughout the day in western Colorado and the cold front passed the Tract C-b region late in the afternoon. A few scattered showers fell during the evening.

The upper flow began to change from zonal to meridional characteristics on the 23rd. A strong short wave trough dug southward over the Intermountain Region on this day while upper ridges built northward over the eastern and western portions of the nation. On the surface, a maritime polar front extended southward into Texas from a low in Kansas. In addition, a relatively strong continental polar cold front rushed southward through the central Plains states. High pressure dominated the East and the West. Precipitation fell in the Pacific Northwest, the Rockies, and throughout the central portion of the nation. Some snow and rain fell during the early morning in western Colorado, but skies cleared during the late morning hours and remained clear for the rest of the 23rd.

The upper circulation became meridional on the 24th as the troughs and ridges amplified rapidly. Long wave ridges were located along the Atlantic coast and in the western United States while long wave troughs dug southward through the central United States and near 140°W longitude. The maritime and continental polar cold fronts of the 23rd merged into one cold front which extended from the Great Lakes to southern Texas. A weak high pressure system dominated the western half of the country. Precipitation on this day was confined to the Pacific Northwest and along the length of the cold front.

Western Colorado enjoyed fair skies and cool temperatures because of the high pressure system centered in northwestern Colorado.

Meteorological systems moved rapidly on November 25th, as the long wave trough through the central United States moved eastward, as did the upstream ridge and trough. As a result, a strong short wave pushed eastward to a position from Washington to southern California by the morning of the 25th. The surface maritime polar cold front accompanying this short wave extended from Idaho to central California at this time and was moving eastward rapidly. High pressure dominated the central portion of the United States as precipitation was confined to the Atlantic seaboard, the Northwest, and the Pacific Northwest. Western Colorado remained fair throughout the day, with some high cloudiness advecting over the area during the morning. Skies were clear during the remainder of the day. The maritime polar cold front passed through the Tract C-b region during the evening of the 25th, lowering temperatures somewhat.

The eastward progression of the long wave systems continued on the 26th of November. Large amplitude troughs were located in New England and on an Alberta, Canada, to Texas axis, while sharp ridges extended from Missouri to Minnesota and northward into Canada and also long the Pacific coast, northward into British Columbia. A cold front extended southward from Canada into Minnesota and from there into Oklahoma, at which point it curved westward into New Mexico. High pressure cells dominated the Ohio and Mississippi Valley regions and also the western third of the country. Precipitation was scattered throughout the northern third of the nation. Clear skies and cool temperatures prevailed in the Tract C-b area.

Short waves and upper level lows moving eastward in the meridional long wave troughing pattern were the major meteorological forces on November 27th. Upper lows were centered just north of Maine, just north of Minnesota, and in southern Washington on the morning of the 27th. One cold front extended from the Great Lakes to Tennessee and southwestward into central Texas on this day while another maritime polar cold front extended from Oregon southwestward into northern California. A weak high pressure system dominated the Plains states and the Intermountain Region. Precipitation was confined to the Great Lakes region, New England, and the Pacific Northwest. High cloudiness increased throughout the day in western Colorado in advance of the approaching upper low and surface cold front. A middle overcast covered the Tract C-b area by evening; temperatures remained cool.

Rapid changes took place on November 28th. The upper low in Washington moved to a position over northern Utah and strengthened, while the other two upper lows over North America also strengthened but remained stationary. Meanwhile, the upper ridge over the Pacific Northwest amplified dramatically, which caused surface anticyclogenesis in southern Canada and the northwestern portion of the United States. The development of this large cold continental polar high cell caused a new frontal system to form from the Texas Panhandle westward to northern Arizona. Cold air streamed southward over the northwestern half of the United States. Precipitation, mainly in the form of snow, occurred in the Great Lakes region and in the central Rockies and Intermountain Region. Western Colorado was cloudy throughout the 28th, with intermittent snow showers. Rather cold air advected into the area during the day. Clearing took place in western Colorado during the evening.

The deep long wave trough and strong upper ridge progressed eastward during the 29th as a transition to zonal flow over the United States began. The upper trough extended from Minnesota to New Mexico while the upper ridge extended northward from California to Alberta, Canada. The upper low over Utah filled as the trough was propelled eastward. A cold front extended from Tennessee to Arkansas and then into southern Texas. A large cold high cell centered just north of North Dakota dominated the weather over the western two-thirds of the nation. Precipitation, much of it in the form of snow, occurred from the Rockies eastward to the Mississippi Valley and southward to the Gulf of Mexico, and snow flurries occurred in the lee of the Great Lakes. Skies were clear throughout the day in the Tract C-b region, but very cold air continued to affect the area.

By November 30th, the upper circulation had changed to a basically zonal pattern. An intense upper low was centered over northern Missouri with a strong upper ridge over the Intermountain Region. On the surface, a large, complex low system was beginning to organize over the Southeast while a strong ridge of high pressure extended from North Dakota to southern Texas. Cold continental polar air and high pressures dominated the western two-thirds of the United States. The eastern half of the United States was covered by cloudiness and precipitation. Snows occurred in the Rockies. Heavy snow fell in Missouri, Illinois, and Iowa. Skies were fair throughout the day in western Colorado but very cold air persisted in the Tract C-b region.

**B. Summary of Meteorological Statistics in
Western Colorado during November**

The area of western Colorado in the vicinity of the Tract C-b had below normal temperatures and above normal precipitation during the month of November. The area experienced five cold frontal passages during November (November 8, 13, 18, 22, and 25). In addition, the passage of an upper trough on November 28th brought extremely cold air into the region. Precipitation fell in the area on twelve separate days of November (November 1, 2, 3, 4, 8, 9, 10, 18, 19, 22, 23, and 28). Of these precipitation occurrences, five involved snowfall in the area of the Tract C-b (November 1, 3, 19, 23, and 28).

In general, the first twelve days of November had slightly below normal temperatures. From the 13th through the 26th, temperatures were generally near to slightly above normal. From the 28th through the 30th of November, the Tract C-b experienced temperatures well below normal.

The region experienced about 75 percent of the possible insolation during the month. Cloud cover (all types, but mostly high clouds) averaged 5.1 out of a possible 10 during the period from sunrise to sunset in the region and 4.5 out of a possible 10 for all 24-hour midnight to midnight periods during the month. The area experienced a total of twelve clear days, six partly cloudy days, and twelve cloudy days during November. Thunderstorms were scattered over the region on November 18th. Grand Junction, Colorado, about sixty miles to the south-southwest of the Tract C-b, measured 1.18 inches of precipitation during November, which is .57 inches above normal for the month.

The following is a summary of all official FKUS Air Stagnation Narratives issued by the National Weather Service during November which pertain to the Tract C-b region. These messages were received over the National Weather Service's "C" Service Teletype Circuit, to which Radian subscribes via a terminal in its Austin facilities.

- November 7th: "Gradual flattening of the upper ridge over the Southwest in conjunction with the surface high will result in localized marginal dispersion over sections of California, eastern Nevada, Utah, western Colorado, Arizona and New Mexico today..."
"Localized dispersion problems due to weak low level gradients through the interior Southwest will improve rapidly after the morning of November 8th..."
- November 13th: "The ridge over the Pacific Northwest is forecast to weaken and be forced southeast, spreading stagnation into the Great Basin and Idaho tonight...stagnation in the Great Basin will affect mainly night and morning dispersion conditions."
- November 14th: "A short wave moving into Colorado by Friday evening will cause weakening of the ridge in the West..."
- November 22nd: "In the wake of the upper trough moving out of the Rockies, computerized upper level progs show some ridging from California to Colorado by the morning

of the 24th. This, in conjunction with the surface high and its associated light low level winds, may result in some marginal dispersion conditions in the usually susceptible areas in sections of California, Nevada, Utah, and Colorado during the next 36 to 48 hours. Low mixing heights during the late night and early morning hours will also support this stagnation although transport winds will generally be above the required minimums..."

C. Discussion of the Meteorological
Conditions in the Monitoring
Network during November

Cold temperatures and periods of snowfall became rather common in the ambient air monitoring network in and around the Tract C-b during the month of November. Average temperatures in the network ranged from 26.7°F at Trailers 020 and 021 in the Piceance Creek Valley to 33.3°F at the 200-foot level of the meteorological tower at Trailer 023 on the Tract C-b itself. Winds during the month were moderate in force on the plateau around the meteorological tower and rather light in the Piceance Creek Valley, where katabatic and anabatic (downslope and upslope, respectively) circulation cells accounted for much of the wind. Monthly average relative humidities both on the plateau and in the valley ranged between 60 and 70 percent. Vector wind directions were southeasterly in the Piceance Creek Valley where the flow is constrained by the valley walls and south-southwesterly on the plateau, where synoptic-scale pressure gradient forces normally control the direction and speed of the wind.

The katabatic circulation cell continued to exert a large influence on the meteorology of the Piceance Creek Valley during November, although the anabatic, or upslope, circulation cell which normally develops during the daylight hours was almost non-existent during the month. The katabatic flow was normally strongest, about 10 miles per hour sustained winds, at Trailer 022 at the eastern end of the monitoring network in the valley. The strongest drainage winds at this station normally occurred from 0100 to 0500 hours in the morning. When northwesterly gradient winds extended down into the valley, they were normally strongest at Trailer 021, at the western end of the valley monitoring network.

Vector resultant winds for the valley stations during the month were: 1.4 miles per hour from 138.6° at Trailer 020, 1.3 miles per hour from 123.2° at Trailer 021 and 3.2 miles per hour from 108.9° at Trailer 022. The highest five-minute average winds recorded during the month in the valley were 19 miles per hour at Trailer 020 on the 18th, 23 miles per hour at Trailer 021 on the 28th, and 18 miles per hour at Trailer 022 on the 27th. The highest daily average winds occurred on November 28th.

Relative humidities were rather uniform in the Piceance Creek Valley during the month. The monthly average relative humidities ranged from 69.9% at Trailer 022 to 62.6% at Trailer 021. Trailer 020 was intermediate with a 66% average relative humidity. The highest daily average relative humidities during the month occurred on November 21st.

Nighttime temperatures once again were coldest at Trailer 021 during November, due to the light winds, dry air, and strong radiational cooling which normally prevailed at this site. The other valley sites also experienced strong radiational cooling conditions, but not to the extent that they developed at Trailer 021. On a clear night with light winds, the air at Trailer 021 was normally 5 degrees colder during the early morning hours than it was at Trailer 020, 10 degrees colder than the air at Trailer 022, and 15 degrees or more colder than the air on the plateau near the meteorological tower. It can therefore be said that nighttime temperatures on clear nights generally increased as one progressed eastward up the Piceance Creek Valley. However, on nights when winds were strong, skies were cloudy, and precipitation fell, the strong radiational cooling did not develop and temperatures were rather uniform throughout the monitoring network, from the valley to the plateau.

Monthly average temperatures in the valley ranged from 26.7° at both Trailers 020 and 021 to 28.9° at Trailer 022. The highest daily average temperatures in the valley during the month occurred on November 22nd, while the lowest daily average temperatures were experienced on November 29th. The highest five-minute maximum temperature in the valley during November was 54°F at Trailer 022 on November 21st. Daytime maximum temperatures in the valley were generally highest at Trailer 022. The lowest temperatures recorded in the valley were -17°F and -16°F , both occurring at Trailer 021, on November 29th and 30th, respectively.

On the plateau, meteorological conditions were often somewhat different from those in the Piceance Creek Valley. The diurnal variations in temperature and wind direction which were so prominent in the valley were not of as much importance on the plateau. The diurnal range of temperatures was much smaller within the Tract C-b itself because of three factors: (1) the plateau was not affected by the katabatic circulation cell to the extent that it affected the valley, (2) radiational cooling conditions were not as strongly developed on the plateau as they were in the valley, and (3) thermally induced vertical mixing of the air during clear or partly cloudy days resulted in rather uniform afternoon temperatures throughout the monitoring network. The fifteen degree differences in temperature which existed during the night were not present during the day. During cloudy, windy, or wet conditions, however, the temperatures were approximately the same at any given time, whether it was a meteorological tower level or a site in the valley.

Winds were generally much stronger on the plateau than they were in the valley. This can be attributed to the fact that the synoptic-scale pressure gradient force winds which affect the plateau seldom extend into the valley because of the terrain constraints. The tower site, in particular, is often

affected by very strong winds which are affected only minimally by the terrain and its frictional dissipation forces.

The meteorological tower continued to monitor some remarkable meteorological effects during November. On days with light winds and little, if any, pressure gradient forces, the winds varied considerably in direction with height and the winds were normally strongest at the 100-foot level. On days with strong south-southwesterly winds, the winds increased in speed by about 25% from the 30-foot level to the 200-foot level and generally veered in direction (progression in a clockwise direction) by about 10 degrees from 30-feet to 200-feet. When strong northerly winds prevailed, about a 20% increase in speed from 30-feet to 200-feet occurred and the winds generally backed in direction (counter-clockwise) with increasing height. However, these phenomena are consistent with meteorological rules.

When windy, cloudy, or rain/snow conditions existed, temperatures generally varied little with height at the meteorological tower, a situation which is to be expected because of the neutral stability conditions which prevail under such conditions. However, on clear days or nights when winds were fairly light, the lowest 100 feet of the surface boundary layer on the plateau were often decoupled from the atmosphere above it. That is, the ground-based radiation inversion generated during the night often was confined to the lowest 100 feet, with the temperature decreasing with height above that level. Conversely, during the daytime hours on sunny days, the temperature normally decreased with height up to the 100-foot level. Above that height, however, an inversion layer sometimes existed. On such occasions, therefore, the mixing depth over the meteorological tower site was only 100 feet. This elevated inversion situation was not a common occurrence,

but occurred often enough during November to merit some mention.

The average vector resultant wind speed increased with height at the meteorological tower. The resultant speed was 3 miles per hour at 30-feet, 3.4 miles per hour at 100-feet, and 4 miles per hour at 200-feet. The vector resultant wind directions were 202.4 degrees at 30-feet, 189.9 degrees at 100-feet, and 214.0 degrees at 200-feet. For purposes of comparison, Trailer 024, about 1 mile north of the meteorological tower site, had a vector resultant wind direction of 145.5 degrees and a resultant speed of 1.1 miles per hour.

The highest daily average wind speeds on the plateau, up to 18.6 miles per hour at the 200-foot level, were recorded on November 18th, while the lowest daily average wind speeds on the plateau occurred on November 9th. The highest five-minute average wind speeds at the meteorological tower occurred on November 25th.

The monthly average temperatures at the tower site increased with height, ranging from 31.8°F at 8 feet (partially because of radiational cooling effects) to 33.3°F at 200 feet. The 30-foot level averaged 32.4°F and the 100-foot level averaged 33.1°F. The highest daily average temperatures during the month, 41.2°F to 42.6°F, occurred on November 21st. The coldest daily average temperatures on the plateau were recorded on November 29th, with the daily averages ranging from 13.6°F to 15.3°F. The highest five-minute average temperature recorded at the tower site during the month was 53°F at the 8-foot level on the 21st. The lowest temperature recorded on the plateau was 3°F, at both the 8- and 200-foot levels on the 29th.

Relative humidities were fairly uniform over the plateau during the month, averaging in the low 60's at all four tower levels and at Trailer 024. November 3rd and 9th were the most humid days of the month on the plateau, while the 21st was the driest.

Solar radiation measurements showed a direct correlation with cloud cover, atmospheric moisture, turbidity of the air, and solar elevation during November. The highest hourly totals of solar radiation received at the meteorological tower during the month were 49.20 langleys from 1100 to 1200 hours on November 29th and 48.50 langleys from 1000 to 1100 hours on November 5th.

VI. DATA PRESENTATION AND SUMMARY

This section includes summaries for various recorded data at the monitoring sites. The data presentations indicate the variability of recorded concentrations and meteorological parameters with location and time. In addition, correlation of concentration with wind direction is shown. All data channels except suspended particulates (24-hour samples) are sampled once each second, but recorded as five-minute arithmetic averages of the one-second samples. In some cases, the one-second sampling rate is faster than the time required for the instrument to process a sample; however, these instruments have sample-and-hold circuits that retain the previous value until updated. This averaging technique tends to smooth the recorded parameters and reduce the effects of electronic noise inherent in any electronic instruments.

The random noise is present both from the recording instruments and quantization in the analog-to-digital conversion. The lower threshold for all analytical instruments is twice the maximum noise level generated by the instruments. This lower threshold is 5 ppb for all instruments except the ozone analyzer, for which it is 0.5 ppb. Any values appearing in the presentations that are less than the threshold indicate minimal levels and should not be construed as absolute levels because of recording system noise. In addition, averages of the random noise tend toward zero, and any zero entries appearing in the data presentations do not necessarily indicate absolute zero concentration.

All pollutant data (except for particulate data) is taken at the monitoring site in integer parts per billion (ppb) but is presented here in micrograms per cubic meter ($\mu\text{g}/\text{m}^3$)

assuming standard temperature and pressure of 25°C and 760 mmHg (1013.2 millibars), respectively. The scale factors required to convert $\mu\text{g}/\text{m}^3$ at standard conditions back to ppb for the various pollutants are given in the following table.

POLLUTANT	TO CONVERT $\mu\text{g}/\text{m}^3$ AT 25°C AND 760 mmHg TO ppb MULTIPLY BY
NO_x	.534
NO	.534
NO_2	.534
SO_2	.384
H_2S	.723
THC	1.536
CH_4	1.536
CO	.877
O_3	.512

It should also be noted that NO is measured as NO_2 . No regulations presently exist for NO, and it can be oxidized to NO_2 quite readily so it is more meaningful to report the NO_2 equivalent of the NO. In addition, it permits simple subtraction of NO from NO_x to obtain NO_2 . It also should be noted that total hydrocarbons are measured as the equivalent methane value.

Table IV displays the quarterly statistics for each monitoring station. All averages are arithmetic except for suspended particulates which are geometric means. The maximum average for various averaging times is also shown. The averaging times are selected to provide comparison to ambient air standards. It should also be pointed out that the maximum 1-hour SO₂ concentration is actually a thirty-minute average. The 24-hour particulate "average" is actually one sample taken from midnight to midnight, and the 3-hour hydrocarbon average covers only 6:00 to 9:00 a.m. For averaging times less than or equal to three hours, the sliding average is stepped one five-minute sample at a time. For longer averaging times the step size is twelve samples or one hour. For averaging times less than or equal to one hour, 100 percent of the five-minute samples must be present to compute an average. Averaging times greater than one hour require 90 percent. Whether or not a sliding average is computed is solely determined by the number of samples present in that averaging time.

Table V demonstrates the distribution of particulate concentration. For each site, the number of recorded samples occurring in each of fourteen classes is displayed. In addition, the geometric mean of particulate samples at each site is shown.

Table VI presents daily averages for all of the baseline gases that are monitored, and for total suspended particulates. The averages are grouped by month and individual location. A blank entry in this table indicates that less than 50 percent of the five-minute samples were recorded for that particular day. (Note: Particulate samples are 24-hour samples.) All concentrations are in micrograms per cubic meter.

To demonstrate the functional dependence of recorded parameters upon wind direction, Table VII shows pollutant concentration displayed in a bi-variate distribution with wind direction. The tables display the total number of five-minute samples occurring in each concentration and wind speed class. The mean concentration for all samples occurring in each wind class are also shown. This distribution demonstrates the dependence of high pollutant concentrations upon wind direction.

Table VIII, which depicts the stability wind roses for September, October, and November, and the quarter covering those three months, was generated by means of the STAR Program. An inspection of the stability wind roses reveals that of the six stability classes, "A", "B", "C", "D", "E", and "F", "D" and "F" stabilities were rather common during the period, while "A" stability occurred only rarely in the vicinity of the Tract C-b. The STAR Program incorporates meteorological techniques and methodologies developed by Dr. F. Pasquill and D. Bruce Turner to produce a bi-variate frequency distribution of six wind speed classes and sixteen wind direction sectors as a function of six separate stability classes.

The wind speed classes in this Pasquill formulation correspond to the first six wind speed (or force) categories of the commonly used Beaufort Wind Scale, which was devised by Admiral Beaufort of the British Navy in the early nineteenth century. The wind speed classes in these tables are constructed using knots (1.16 miles per hour) as the unit of measurement. The sixteen wind direction classifications are referenced to true north, with each direction representing a $22\frac{1}{2}$ degree sector of the full 360 degree circle.

The wind direction and wind speed measurements used in this stability wind rose distribution were obtained from the 100-foot measurement level of the meteorological tower (Trailer 023) on the Tract C-b. The tower wind data was used in preference to wind data from the valley stations or other meteorological sources because that area of the plateau was deemed to experience wind flows which were most applicable to the points of interest in pollutant modelling; terrain factors were also of less importance in the wind speeds and directions experienced at this location, so that synoptic-scale meteorological features exerted a larger influence on the flow. The 100-foot level wind data was used because the wind instruments at this level had more "up" time over the quarter under consideration here. The wind data at the 100-foot level may differ slightly from that at the 30-foot level or the 200-foot level (mainly because of the variability of wind direction with height during periods of light and variable winds and the general increase of wind speed with height which accompanies gradient winds that exceed 7 or 8 knots), but the differences will not affect the stability wind roses appreciably. Therefore, the wind data used here should be considered to be highly representative of the plateau region.

The radiation data which made up the other half of the data input to the STAR Program was obtained from cloud cover and ceiling data from the Grand Junction, Colorado, National Weather Service Office. The inputs which combine to determine the radiation index using STAR Program methods are: (1) cloud cover in tenths, (2) cloud height above the ground if a ceiling exists, and (3) solar elevation (or time of day for nighttime applications). The cloud data from Grand Junction was used because it was deemed to be the most representative data available in the area of the Tract C-b (approximately 60 miles to the south-southwest). Moreover,

since the majority of the cloudiness in this area during the quarter was of the middle and/or high varieties, which are normally uniform in their coverage characteristics and heights over a region while at the same time extending over a large area (a synoptic-scale feature) during their occurrence, the use of Grand Junction cloud data is deemed to be meteorologically sound. Periods of clear skies should also be uniform in spatial and temporal extent in the Grand Junction - Tract C-b expanse. Some slight variances in cloud coverage amounts could have occurred during periods of local storms, low cloudiness, or terrain-induced cloudiness and fog. However, there was probably only a minimal number of such occurrences, so that the stability wind roses are applicable to the Tract C-b region.

This method of radiation index determination (use of cloud cover data from Grand Junction) was chosen over the pyranometer data recorded on-site because the pyranometer data was not available for the entire quarter. Radian recommends the use of pyranometer data for daytime hours, and the change in temperature versus height (lapse rate from met tower) for nighttime to determine the radiation index. This method will be used in future reports.

BEAUFORT WIND SCALE FOR OBSERVATIONS AT LAND STATIONS

Force	Explanatory Title	Specification for Use	Corresponding Limits of Wind Speed at 10 meters ab. grd.				
			Mi/hr.	Knots	Km/hr.	M/sec.	Ft/sec.
0	Calm.....	Smoke rises vertically.....	<1	<1	<1	0.3	1
1	Light air.....	Direction of wind shown by smoke drift, but not by wind vanes.....	1-3	1-3	1-5	0.3-1.5	1-5
2	Light breeze.....	Wind felt on face; leaves rustle; ordinary vane moved by wind.....	4-7	4-6	6-11	1.6-3.3	6-11
3	Gentle breeze.....	Leaves and small twigs in constant motion; wind extends light flag.....	8-12	7-10	12-19	3.4-5.4	12-18
4	Moderate breeze...	Raises dust and loose paper; small branches are moved.....	13-18	11-16	20-28	5.5-7.9	19-26
5	Fresh breeze.....	Small trees in leaf begin to sway; wavelets formed on inland waters.....	19-24	17-21	29-38	8.0-10.7	27-35
6	Strong breeze.....	Large branches in motion; whistling heard in telegraph wires; umbrellas used with difficulty.....	25-31	22-27	39-49	10.8-13.8	36-45
7	High wind.....	Whole trees in motion; inconvenience felt when walking against wind.....	32-38	28-33	50-61	13.9-17.1	46-56
8	Fresh gale.....	Breaks twigs off trees; generally impedes progress.....	39-46	34-40	62-74	17.2-20.7	57-68
9	Strong gale.....	Slight structural damage occurs (chimney pots and slates removed).....	47-54	41-47	75-88	20.8-24.4	69-83
10	Whole gale.....	Seldom experienced inland; trees uprooted; considerable structural damage occurs..	55-63	48-55	89-102	24.5-28.4	81-93
11	Storm.....	Very rarely experienced; accompanied by widespread damage.....	64-72	56-63	103-117	28.5-32.6	94-106
12	Hurricane.....		73-82	61-71	118-133	32.7-36.9	107-121
13			83-92	72-80	134-149	37.0-41.4	122-136
14			93-102	81-89	150-166	41.5-46.1	137-151
15			101-114	90-99	167-183	46.2-50.9	152-166
16			115-125	100-108	184-201	51.0-56.0	167-183
17			126-136	109-118	202-220	56.1-61.2	184-201

Source: Table 36 (p. 119) in R. J. List (1951); Smithsonian Meteorological Tables; Smithsonian Miscell. Coll. Vol. 114.

Table IX demonstrates the diurnal variation of various recorded parameters. Hourly averages are determined by arithmetically averaging five-minute samples, except for wind direction averages which are computed vectorially assuming unit vector magnitudes. Totals in the diurnal wind direction tables are vector averages of the columns and rows. For all parameters, a blank entry in the diurnal variation table indicates that less than half (i.e., less than 6) of the five-minute samples for that hour are present.

Times given in the data presentation are Mountain Daylight Saving Time until toward the end of the month of October when the computer clocks were manually reset to Mountain Standard Time. When the computer clocks were set back one hour, one hour's worth of data was overwritten.

To facilitate comparison of recorded concentrations to ambient air quality standards, the following regulations are presented.

FEDERAL AND COLORADO STANDARDS

TABLE VIII

STABILITY WIND ROSE DIAGRAMS

WIND DISTRIBUTION BY PASQUILL STABILITY CLASSES (STAR PROGRAM) (6 Classes) (8 Obs/Day)

Data are presented by stability classes and also combined for the period indicated; first, as a bivariate frequency distribution of wind direction vs. wind speed, and second, as normalized values (i.e., relative frequency). Stability classes used are based on

Pasquill's class structure (see Journal of Applied Meteorology, February 1964), as follows:

Pasquill Stability Class	Identified in lower left corner in this tabulation as	Definition
1	A	Extremely Unstable
2	B	Unstable
3	C	Slightly Unstable
4	D	Neutral
5	E	Slightly Stable
6-7	F	Stable to Extremely Stable

Average wind speed in knots, to tenths, for each direction and each speed class. Overall average wind speed is computed by

$$\frac{\text{Sum of wind speed}}{\text{Number of occurrences}}$$

NUMBER OF OCCURRENCES: Number of DIR/SPD observations, plus number of calms (winds are tabulated to 16 points; speeds are in knots.)

RELATIVE FREQUENCY OF OCCURRENCES: $\frac{\text{Number of occurrences/stability class}}{\text{Total number of observations}}$

TOTAL NUMBER OF OBSERVATIONS: Number of observations in each, month, season, annual or period.

TOTAL RELATIVE FREQUENCY OF OBSERVATIONS: $\frac{\text{Total number of observations}}{\text{Total number of observations}} = 1.00000$

This normalized (relative frequency) table is self explanatory, except that the calm values have been distributed in the 0-3 speed category based on the number of observations in speed categories 0-3 and 4-6.

A STABILITY CLASSIFICATION BASED ON HOURLY AIRPORT OBSERVATIONS

The following explanation of the Pasquill Stability classification has been extracted from an article by D. Bruce Turner in the February 1964 Journal of Applied Meteorology.

This system of classifying stability on an hourly basis for research in air pollution is based upon work accomplished by Dr. P. Pasquill of the British Meteorological Office (1961). Stability near the ground is dependent primarily upon net radiation and wind speed. Without the influence of clouds, insolation (incoming radiation) during the day is dependent upon solar altitude, which is a function of time of day and time of year. When clouds exist their cover and thickness decrease incoming and outgoing radiation. In this system insolation is estimated by solar altitude and modified for existing conditions of total cloud cover and cloud ceiling height. At night estimates of outgoing radiation are made by considering cloud cover. This stability classification system has been made completely objective so that an electronic computer can be used to compute stability classes. The stability classes are as follows: 1) Extremely unstable, 2) Unstable, 3) Slightly unstable, 4) Neutral, 5) Slightly stable, 6) Stable, 7) Extremely stable. Table A-1 gives the stability class as a function of wind speed and net radiation. The net radiation index ranges from 4, highest positive net radiation (directed toward the ground), to -2, highest negative net radiation (directed away from the earth). Instability occurs with high positive net radiation and low wind speed, stability with high negative net radiation and light winds, and neutral conditions with cloudy skies or high wind speeds.

The net radiation index used with wind speed to obtain stability class is determined by the following procedure:

- 1) If the total cloud cover is 10/10 and the ceiling is less than 7000 feet, use net radiation index equal to 0 (whether day or night).
- 2) For night-time (night is defined as the period from one hour before sunset to one hour after sunrise):
 - a) If total cloud cover $\leq 4/10$, use net radiation index equal to -2.
 - b) If total cloud cover $> 4/10$, use net radiation index equal to -1.

3) For daytime:

- a) Determine the insolation class number as a function of solar altitude from Table A-2.
- b) If total cloud cover $\leq 5/10$, use the net radiation index in Table A-1 corresponding to the insolation class number.
- c) If cloud cover $> 5/10$, modify the insolation class number by following these six steps:
 - 1) Ceiling < 7000 ft, subtract 2.
 - 2) Ceiling ≥ 7000 ft but $< 16,000$ ft, subtract 1.
 - 3) Total cloud cover equal 10/10, subtract 1. (This will only apply to ceilings ≥ 7000 ft since cases with 10/10 coverage below 7000 ft are considered in item 1 above.)
 - 4) If insolation class number has not been modified by steps (1), (2), or (3) above, assume modified class number equal to insolation class number.
 - 5) If modified insolation class number is less than 1, let it equal 1.
 - 6) Use the net radiation index in Table A-1 corresponding to the modified insolation class number.

Since urban areas do not become as stable in the lower layers as non-urban areas, stability classes 5, 6 and 7 computed using the STAB program may be combined into a single class (5), or classes 6 and 7 may be combined and identified as class 6.

A STABILITY CLASSIFICATION BASED ON HOURLY AIRPORT OBSERVATIONS (CONT'D) (STAR PROGRAM)

TABLE A-1. STABILITY CLASS AS A FUNCTION OF NET RADIATION AND WIND SPEED

WIND SPEED (KNOTS)	NET RADIATION INDEX						
	4	3	2	1	0	-1	-2

ATTACHMENT A

Particulate loadings at the Tract C-b monitoring stations are determined daily by use of Hi-Vol filters. The standard fiberglass filters are used for routine sampling. Supplementary filters are taken every sixth day at Trailer 023 to permit actual chemical analysis of the particulate matter. Special low background cellulose filters are used for this purpose.

Two types of samples are taken:

1. A quarterly composite to determine average concentrations.
2. A spot sample to detect any gross short-term variations from the average.

Half of each filter is retained to permit detailed examination if any unforeseen problems or high levels occur. The filters are analyzed for trace elements using a spark source mass spectrometry survey scan and for gross α and β radioactivity.

The results for the past quarter are attached. The levels reported are quite low with no problems evident. Units reported are ppm for the trace elements and pCi/gm for radioactivity.

RADIOACTIVITY

<u>Sample</u>	<u>Gross Alpha $\pm$ precision*</u>		<u>Gross Beta $\pm$ precision*</u>	
	<u>pCi/cm²</u>	<u>pCi/gram</u>	<u>pCi/cm²</u>	<u>pCi/gram</u>
